14.8 Spin Angular Momentum ..... 000
14.9 Conclusion ..... 000

We treat hydrogenic atoms with group theory.

### 16.1 Introduction

### 16.2 Two Important Principals of Physics

There are two principles of fundamental importance that allow group theory to be used in profoundly important ways in physics. These are the Principle of Relativity and the Principle of Equivalence. We give a brief statement of both using a variant of Dirac notation.

Principle of Relativity (of Observers): Two observers, $S$ and $S^{\prime}$, describe a physical state $|\psi\rangle$ in their respective coordinate systems. They describe the state by mathematical functions that are $\langle S \mid \psi\rangle$ and $\left\langle S^{\prime} \mid \psi\right\rangle$. The two observers know the relation between their coordinate systems. The mathematical prescription for transforming from one to the other coordinate system is $\left\langle S^{\prime} \mid S\right\rangle$. The set of transformations among observers forms a group. If observer $S^{\prime}$ wants to determine what observer $S$ has seen, he applies the appropriate transformation to his mathematical functions to determine how $S$ has described the system:

$$
\begin{equation*}
\langle S \mid \psi\rangle=\left\langle S \mid S^{\prime}\right\rangle\left\langle S^{\prime} \mid \psi\right\rangle \tag{16.1}
\end{equation*}
$$

The Principle of Relativity of Observers is a statement that the functions determined by $S^{\prime}$ in this fashion are exactly the functions used by $S$ to describe the state $|\psi\rangle$.

Principle of Equivalence (of States): Two observes $S$ and $S^{\prime}$ observe a system, as above. If

- "the rest of the universe"
- "looks the same"
to both $S$ and $S^{\prime}$, then $S$ can use the mathematical functions $\left\langle S^{\prime} \mid \psi\right\rangle$ written down by $S^{\prime}$ to describe a new physical state $\left|\psi^{\prime}\right\rangle$

$$
\begin{equation*}
\left\langle S \mid \psi^{\prime}\right\rangle=\left\langle S^{\prime} \mid \psi\right\rangle \tag{16.2}
\end{equation*}
$$

and that state must exist.
In this notation, the transformation of a hamiltonian under a group operation (for example, a rotation in $S O(3)$ ) is expressed by $\left\langle S^{\prime}\right| H\left|S^{\prime}\right\rangle=\left\langle S^{\prime} \mid S\right\rangle\langle S| H|S\rangle\left\langle S \mid S^{\prime}\right\rangle$, the invariance under the transformation $\left\langle S^{\prime} \mid S\right\rangle$ is represented by $\left\langle S^{\prime}\right| H\left|S^{\prime}\right\rangle=\langle S| H|S\rangle$, and the existence of a $2 p_{z}$ state in a system with spherical symmetry implies the existence (by the Principle of Equivalence) of $2 p_{x}$ and $2 p_{y}$ states, as well as arbitrary linear combinations of these three states.

### 16.3 The Wave Equations

Schrödinger's derivation of a wave equation for a particle of mass $m$ began with the relativistic dispersion relation for the free particle: $p^{\mu} p_{\mu}=g_{\mu \nu} p^{\mu} p^{\nu}=(m c)^{2}$. In terms of the energy $E$ and the momentum $\mathbf{p}$ this is

$$
\begin{equation*}
E^{2}-(\mathbf{p} c)^{2}=\left(m c^{2}\right)^{2} \tag{16.3}
\end{equation*}
$$

Interaction of a particle of charge $q$ with the electromagnetic field is described by the Principle of Minimal Electromagnetic Coupling: $p_{\mu} \rightarrow \pi_{\mu}=p_{\mu}-\frac{q}{c} A_{\mu}$, where the four-vector potential $A$ consists of the scalar potential $\Phi$ and the vector potential $\mathbf{A}$. These obey $\mathbf{B}=\nabla \times \mathbf{A}$ and $\mathbf{E}=-\nabla \Phi-\frac{1}{c} \frac{\partial \mathbf{A}}{\partial t}$. For an electron $q=-e$, where $e$ is the charge on the proton, positive by convention. In the Coulomb field established by a proton, $\Phi=e / r$ and $\mathbf{A}=\mathbf{0}$, so that $E \rightarrow E+e^{2} / r$. Here $r$ is the proton-electron distance. The Schrödinger prescription for converting a dispersion relation to a wave equation is to replace $\mathbf{p} \rightarrow(\hbar / i) \nabla$ and allow the resulting equation to act on a spacial function $\psi(\mathbf{x})$. This prescription results in the wave equation

$$
\begin{equation*}
\text { Klein-Gordon Equation: } \quad\left\{E^{2}-\left(m c^{2}\right)^{2}+2 E\left(\frac{e^{2}}{r}\right)+\left(\frac{e^{2}}{r}\right)^{2}-(-i \hbar c \nabla)^{2}\right\} \psi(x)=0 \tag{16.4}
\end{equation*}
$$

Schrödinger solved this equation, compared its predictions with the spectral energy measurements on the hydrogen atom, was not convinced his theory was any good, and buried this approach in his desk drawer.

Sometime later he reviewed this calculation and took its nonrelativistic limit. Since the binding energy is about 13.6 eV and the electron rest energy $m c^{2}$ is about $510,000 \mathrm{eV}$, it makes sense to write $E=m c^{2}+W$, where the principle part of the relativistic energy $E$ is the electron rest energy and the nonrelativistic energy $W$ is a small perturbation of either ( $\simeq 0.0025 \%$ ). Under this substitution, and neglecting terms of order $\left(W / m c^{2}\right)^{2}$, we obtain the nonrelativistic form of Eq. (2):

$$
\begin{equation*}
\text { Schrödinger Equation: } \quad\left\{\frac{\mathbf{p} \cdot \mathbf{p}}{2 m}-\frac{e^{2}}{r}-W\right\} \psi(\mathbf{x})=\left\{-\frac{\hbar^{2}}{2 m} \nabla^{2}-\frac{e^{2}}{r}-W\right\} \psi(\mathbf{x})=0 \tag{16.5}
\end{equation*}
$$

Eq.(16.4) is now known as the Klein-Gordon equation and its nonrelativistic limit Eq.(16.5) is known as the Schrödinger equation, although the former was derived by Schrödinger before he derived his namesake equation.

Remark: Schrödinger began his quest for a theory of atomic physics with Maxwell's Equations, in particular, the eikonal form of these equations. It is no surprise that his theory inherits key characteristics of electromagnetic theory: solutions that are amplitudes, the superposition principle for solutions, and interference effects that come about by squaring amplitudes to obtain intensities. Had he started from classical mechanics, there would be no amplitude-intensity relation and the only superposition principle would have been the superposition of forces or their potentials. The elegant but forced relation between Poisson brackets and commutator brackets $([A, B] / i \hbar=\{A, B\})$ is an attempt to fit quantum mechanics into the straitjacket of classical mechanics.

### 16.4 Quantization Conditions

The standard approach to solving partial differential equations is to separate variables. Since the two equations derived above have spherical symmetry, it is useful to introduce spherical coordinates: $(r, \theta, \phi)$. In this coordinate system the Laplacian is

$$
\begin{gather*}
\mathcal{L}^{2}=\left(\frac{1}{r} \frac{\partial}{\partial r} r\right)^{2}+\frac{\mathcal{L}^{2}\left(S^{2}\right)}{r^{2}}  \tag{16.6}\\
\mathcal{L}^{2}\left(S^{2}\right)=\frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \sin \theta \frac{\partial}{\partial \theta}+\frac{1}{\sin ^{2} \theta} \frac{\partial^{2}}{\partial \phi^{2}} \tag{16.7}
\end{gather*}
$$

The second order differential operator $\mathcal{L}^{2}\left(S^{2}\right)$ is the Laplacian on the sphere $S^{2}$. Its eigenfunctions are the spherical harmonics $Y_{m}^{l}(\theta, \phi)$ and its spectrum of eigenvalues is $\mathcal{L}^{2}\left(S^{2}\right) Y_{m}^{l}(\theta, \phi)=-l(l+$ $1) Y_{m}^{l}(\theta, \phi)$. The integers $(l, m)$ satisfy $l=0,1,2, \cdots$ and $-l \leq m \leq+l$. The negative sign and discrete spectrum characteristically indicate that $S^{2}$ is compact.

The partial differential equations Eqs.(16.4) and (16.5) are reduced to ordinary differential equations by substituting the ansatz

$$
\begin{equation*}
\psi(r, \theta, \phi) \rightarrow \frac{1}{r} R(r) Y_{m}^{l}(\theta, \phi) \tag{16.8}
\end{equation*}
$$

into these equations, replacing the angular part of the Laplacian by the eigenvalue $-l(l+1)$, and multiplying by $r$ on the left. This gives the simple second order ordinary differential equation

$$
\begin{equation*}
\left(\frac{d^{2}}{d r^{2}}+\frac{A}{r^{2}}+\frac{B}{r}+C\right) R(r)=0 \tag{16.9}
\end{equation*}
$$

The values of the coefficients $A, B, C$ that are obtained for the Klein-Gordon equation and the Schrödinger equation are

| Equation | $A$ | $B$ | $C$ |
| :--- | :---: | :---: | :---: |
| Klein-Gordon | $-l(l+1)+\left(e^{2} / \hbar c\right)^{2}$ | $2 E e^{2} /(\hbar c)^{2}$ | $\left[E^{2}-\left(m c^{2}\right)^{2}\right] /(\hbar c)^{2}$ |
| Schrödinger | $-l(l+1)$ | $2 m e^{2} / \hbar^{2}$ | $2 m W / \hbar^{2}$ |

There is a standard procedure for solving simple ordinary differential equations of the type presented in Eq.(16.9). This is the Frobenius method. The steps involved in this method, and the result of each step, are summarized in Table 16.1.

Table 16.1: Left column lists the steps followed in the Frobenius method for finding the squareintegrable solutions of simple ordinary differential equations. Right column shows the result of applying the step to Eq.(16.9).

| Procedure | Result |  |
| :--- | :--- | :--- |
| 1 | Locate singularities | $0, \infty$ |
| 2 | Determine analytic behavior | $r \rightarrow 0: R \simeq r^{\gamma}, \quad \gamma(\gamma-1)+A=0$ |
|  | at singular points | $r \rightarrow \infty: R \simeq e^{\lambda r}, \quad \lambda^{2}+C=0$ |
| 3 | Keep only $\mathcal{L}^{2}$ solutions | $\gamma=\frac{1}{2}+\sqrt{\left(\frac{1}{2}\right)^{2}-A}, \quad \lambda=-\sqrt{-C}$ |
| 4 | Look for solutions with proper | $R=r^{\gamma} e^{\lambda r} f(r)$ |
|  | asymptotic behavior |  |
| 5 | Construct DE for $f(r)$ | $\left[\left(r D^{2}+2 \gamma D\right)+(2 \lambda \gamma+B+2 \lambda r D)\right] f(r)=0$ |
| 6 | Construct recursion relation | $f_{j+1}=-\frac{2 \lambda(j+\gamma)+B}{j(j+1)+2 \gamma(j+1)} f_{j}$ |
| 7 | Look at asymptotic behavior | $f \simeq e^{-2 \lambda r}$ if series doesn't terminate |
|  |  | $\simeq e^{+1 \lambda r}$ if series does terminate $\quad(\lambda<0)$ |
| 8 | Construct quantization condition | $2 \lambda(n+\gamma)+B=0$ or $n+\frac{1}{2}+\sqrt{\left(\frac{1}{2}\right)^{2}-A}=\frac{B}{2 \sqrt{-C}}$ |
|  |  | $E=\frac{m c^{2}}{\sqrt{1+\left(\alpha / N^{\prime}\right)^{2}}} \quad N^{\prime}=n+\frac{1}{2}+\sqrt{\left(l+\frac{1}{2}\right)^{2}-\alpha^{2}}$ |
| 9 | Construct explicit solutions | $W=-\frac{1}{2} m c^{2} \alpha^{2} \frac{1}{N^{2}} \quad N=n+l+1$ |

The energy eigenvalues for the bound states of both the relativistic and nonrelativistic problems are expressed in terms of the radial quantum $n=0,1,2, \cdots$ and the angular momentum quantum number $l=0,1,2, \cdots$, mass $m$ of the electron, or more precisely the reduced mass of the protonelectron pair $m_{\mathrm{red}}^{-1}=m_{e}^{-1}+M_{p}^{-1}$, and the fine structure constant [1]

$$
\begin{equation*}
\alpha=\frac{e^{2}}{\hbar c}=\frac{1}{137.0359997 \underline{96}(70)}=0.00729735253 \underline{13}(38) \tag{16.11}
\end{equation*}
$$

This is a dimensionless ratio of three physical constants that are fundamental in three "different" areas of physics: $e$ (electromagnetism), $\hbar$ (quantum mechanics), and $c$ (relativity). It is the most precisely measured of the physical constants. The bound state energy eigenvalues are

$$
\begin{array}{ll}
\text { Klein-Gordon } \quad E(n, l)=\frac{m c^{2}}{\sqrt{1+\left(\alpha / N^{\prime}\right)^{2}}} & N^{\prime}=n+\frac{1}{2}+\sqrt{\left(l+\frac{1}{2}\right)^{2}-\alpha^{2}}  \tag{16.12}\\
\text { Schrödinger } & W(n, l)=-\frac{1}{2} m c^{2} \alpha^{2} \frac{1}{N^{2}}
\end{array} \quad N=n+l+1
$$

### 16.5 Geometric Symmetry $S O(3)$

Symmetry implies degeneracy.

Figure 16.1: Spectrum of the hydrogen atom, normalized by the energy of the nonrelativistic ground state. The nonrelativistic spectrum is darker. The relativistic spectrum has been computed for $Z=50$.

To see this, assume $g_{i} \in G$ are group operations that leave a hamiltonian $H$ invariant (unchanged in form)

$$
\begin{equation*}
g_{i} H g_{i}^{-1}=H \quad \text { or } \quad g_{i} H=H g_{i} \tag{16.13}
\end{equation*}
$$

When $G$ is a group of geometric transformations the physical interpretation of this equation is as follows. The hamiltonian $H$ has the same form in two coordinate systems that differ by the group operation $g_{i}$. Under this condition, if $|\psi\rangle$ is an eigenstate of $H$ with eigenvalue $E$, then $g_{i}|\psi\rangle$ is also an eigenstate of $H$ with the same energy eigenvalue $E$. The demonstration is straightforward.

$$
\begin{equation*}
H\left(g_{i}|\psi\rangle\right)=\left(H g_{i}\right)|\psi\rangle=\left(g_{i} H\right)|\psi\rangle=g_{i}(H|\psi\rangle)=g_{i}(E|\psi\rangle)=E\left(g_{i}|\psi\rangle\right) \tag{16.14}
\end{equation*}
$$

If $\left|\psi_{1}\right\rangle,\left|\psi_{1}\right\rangle, \ldots,\left|\psi_{n}\right\rangle, \ldots$ are eigenvectors of $H$ with eigenvalues $E_{1}, E_{2}, \ldots, E_{n}, \ldots$, then

$$
\begin{equation*}
g\left|\psi_{i}\right\rangle=\left|\psi_{j}\right\rangle \Gamma_{j i}(g) \tag{16.15}
\end{equation*}
$$

The matrices $\Gamma_{j i}(g)$ form a matrix representation of the group $G$. States $\left|\psi_{i}\right\rangle$ and $\left|\psi_{j}\right\rangle$ have the same energy $E_{i}=E_{j}$ if $\Gamma_{j i}(g) \neq 0$ for at least one group operation $g_{i} \in G$.

The rotation group $O(3)$ leaves the hamiltonian of the hydrogen atom invariant in both the nonrelativistic and relativistic cases. In the nonrelativistic case, $H=\frac{\mathbf{p} \cdot \mathbf{p}}{2 m}-\frac{e^{2}}{r}$. The scalar $\mathbf{p} \cdot \mathbf{p}=$ $-\hbar^{2} \nabla^{2}$ is invariant under rotations, as is also the potential energy term $-e^{2} / r$. Rotation operators can be expressed in terms of the infinitesimal generators of rotations about axis $i: \epsilon_{i j k} x_{j} \partial_{k}$. These geometric operators are proportional to the physical angular momentum operators $\mathbf{L}_{i}=(\mathbf{r} \times \mathbf{p})_{i}=$ $(\hbar / i) \epsilon_{i j k} x_{j} \partial_{k}$. Finite rotations can be expressed as exponentials as follows:

$$
\begin{equation*}
R(\theta)=e^{\epsilon_{i j k} \theta_{i} x_{j} \partial_{k}}=e^{i \theta \cdot \mathbf{L} / \hbar} \tag{16.16}
\end{equation*}
$$

The angular momentum operators $\mathbf{L}=\mathbf{r} \times \mathbf{p}$ share the same commutation relations as the infinitesimal generators of rotations $\mathbf{r} \times \nabla$, up to the proportionality factor $\hbar / i$. The commutation relations are

$$
\begin{equation*}
\left[L_{i}, L_{j}\right]=i \hbar \epsilon_{i j k} L_{k} \tag{16.17}
\end{equation*}
$$

It is useful to construct linear combinations of these operators that have canonical commutation relations of the type described in Chapter 10. To this end we define the raising ( $L_{+}$) and lowering ( $L_{-}$) operators by $L_{ \pm}=L_{x} \pm i L_{y}$. The commutation relations are

$$
\begin{align*}
{\left[L_{z}, L_{ \pm}\right] } & = \pm \hbar L_{ \pm}  \tag{16.18}\\
{\left[L_{+}, L_{-}\right] } & =2 \hbar L_{z} \tag{16.19}
\end{align*}
$$

Up to the proportionality factors $\hbar$, these angular momentum operators are related to the two boson operators as follows: $L_{z}=\hbar \frac{1}{2}\left(a_{1}^{\dagger} a_{1}-a_{2}^{\dagger} a_{2}\right) L_{+}=\hbar a_{1}^{\dagger} a_{2}, L_{-}=\hbar a_{2}^{\dagger} a_{1}$. As a result, the angular momentum operators have matrix representations with basis vectors $\left|\begin{array}{ll}n_{1} & n_{2}\end{array}\right\rangle=\left|\begin{array}{c}j \\ m\end{array}\right\rangle$, with $n_{1}=0,1,2, \ldots, n_{2}=0,1,2, \ldots, n_{1}+n_{2}=2 j, n_{1}-n_{2}=2 m,-j \leq m \leq+j$. These basis vectors describe the finite dimensional irreducible representations of the covering group $S U(2)$ of $S O(3)$. The subset of representations with $j=l$ (integer) describes representations of $S O(3)$.

To see this we construct a coordinate representation of the angular momentum operators. In spherical coordinates $((x, y, z) \rightarrow(r, \theta, \phi)$ with $x=r \sin \theta \cos \phi)$ these operators are

$$
\begin{align*}
l_{z} & =\frac{\hbar}{i} \frac{\partial}{\partial \phi} \\
L_{ \pm} & =\hbar\left( \pm \frac{\partial}{\partial \theta}+i \frac{\cos \theta}{\sin \theta} \frac{\partial}{\partial \phi}\right) \tag{16.20}
\end{align*}
$$

The functions on $R^{3}$ that transform under the angular momentum operators can be constructed from the mixed basis argument:

$$
\begin{gather*}
\langle\theta \phi| L_{-}\left|\begin{array}{c}
l \\
m
\end{array}\right\rangle \\
\downarrow  \tag{16.21}\\
\langle\theta \phi| L_{-}\left|\theta^{\prime} \phi^{\prime}\right\rangle\left\langle\theta^{\prime} \phi^{\prime} \mid{ }_{m}^{l}\right\rangle=\left\langle\theta \phi \mid \underset{m^{\prime}}{l^{\prime}}\right\rangle\left\langle\left.\begin{array}{l}
\downarrow \\
m^{\prime} \\
l^{\prime}
\end{array} L_{-} \right\rvert\, \underset{m}{l}\right\rangle
\end{gather*}
$$

As usual, the intermediate arguments (with 's) are dummy arguments that are summed or integrated over. The symbols in Eq.(16.21) have the following meaning

$$
\left.\begin{array}{rl}
\langle\theta \phi| L_{-}\left|\theta^{\prime} \phi^{\prime}\right\rangle & \begin{array}{l}
\text { Matrix element of the angular momentum shift down operator in the } \\
\\
\\
\text { coordinate representation: } \hbar\left(-\frac{\partial}{\partial \theta}+i \frac{\cos \theta}{\sin \theta} \frac{\partial}{\partial \phi}\right) \delta\left(\cos \theta^{\prime}-\cos \theta\right) \delta\left(\phi^{\prime}-\phi\right) . \\
\left.c_{m^{\prime}}^{l^{\prime}}\left|L_{-}\right| \begin{array}{c}
l \\
m
\end{array}\right\rangle \quad
\end{array} \\
& \text { Matrix element of the angular momentum shift down operator in the } \\
& \text { algebraic representation: } \hbar \sqrt{\left(l^{\prime}-m^{\prime}\right)(l+m)} \delta_{l^{\prime} l} \delta_{m^{\prime}, m-1} . \\
\langle\theta \phi| \\
m
\end{array}\right\rangle \quad \begin{aligned}
& \text { Matrix element of the similarity transformation between the coordinate re- } \\
& \\
& \\
& \\
& \\
& \\
& \\
& Y_{m}^{l}(\theta, \phi) .
\end{aligned}
$$

This relation can be used to show that there are no geometric functions associated with values of the quantum number $j$ that are half integral. It can also be used to constuct the extremal function $Y_{-l}^{l}(\theta, \phi)$ by solving the equation $L_{-} Y_{-l}^{l}(\theta, \phi)=0$ in the coordinate representation (Problem ?.?). Finally, the action of the shift up operators can be used to constuct the remaining functions $Y_{m}^{l}(\theta, \phi)$ through the recursion relation involving both the coordinate and the algebraic representations of the shift up operator $L_{+}$

$$
\begin{equation*}
L_{+} Y_{m}^{l}(\theta, \phi)=Y_{m+1}^{l}(\theta, \phi) \sqrt{(l-m)(l+m+1)} \tag{16.22}
\end{equation*}
$$

The lowest spherical harmonics $(l=0,1,2,3)$ are collected in Table 16.2.

Table 16.2: Spherical harmonics $Y_{m}^{l}(\theta, \phi)$ for low values of $l$ and $m$.

| $m$ | $l=0$ | $l=1$ | $l=2$ | $l=3$ |
| ---: | :---: | :---: | :---: | :---: |
| 0 | $\sqrt{\frac{1}{4 \pi}}$ | $\sqrt{\frac{3}{4 \pi}} \cos \theta$ | $\sqrt{\frac{5}{16 \pi}}\left(3 \cos ^{2} \theta-1\right)$ | $\sqrt{\frac{7}{16 \pi}}\left(5 \cos ^{3} \theta-3 \cos \theta\right)$ |
| $\pm 1$ |  | $\mp \sqrt{\frac{3}{8 \pi}} \sin \theta e^{ \pm i \phi}$ | $\mp \sqrt{\frac{15}{8 \pi}} \cos \theta \sin \theta e^{ \pm i \phi}$ | $\mp \sqrt{\frac{21}{64 \pi}} \sin \theta\left(5 \cos ^{2} \theta-1\right) e^{ \pm i \phi}$ |
| $\pm 2$ |  |  | $\sqrt{\frac{15}{32 \pi}} \sin ^{2} \theta e^{ \pm 2 i \phi}$ | $\sqrt{\frac{105}{32 \pi}} \sin ^{2} \theta \cos \theta e^{ \pm 2 i \phi}$ |
| $\pm 3$ |  |  |  | $\mp \sqrt{\frac{35}{64 \pi}} \sin ^{3} \theta e^{ \pm 3 i \phi}$ |

Remark: The spectrum of the Casimir invariant for the rotation group $S O(3)$, or more specifically the Laplace-Beltrami operator constructed from its infinitesimal generators acting on the sphere parameterized by coordinates $(\theta, \phi)$, is $-l(l+1), l=0,1,2, \ldots$ The fact that the spectrum is negative means that the space, $S^{2}$, on which these operators act, is compact. By the same token, the spectrum of the square of the angular momentum operator, $\mathbf{L} \cdot \mathbf{L}$, is $\hbar^{2} l(l+1)$. This means physically that the inner product of the angular momentum operator with itself is never negative, and is quantized by integer angular momentum values, measured in units of Planck's constant $\hbar$.

### 16.6 Dynamical Symmetry $S O(4)$

Symmetry implies degeneracy.
The greater the symmetry, the greater the degeneracy.
The states of the nonrelativistic hydrogen atom with fixed principal quantum number $N=n+l+1$ are degenerate, with energy $E_{N}=-\frac{1}{2} m c^{2} \alpha^{2} \frac{1}{N^{2}}$. There are $\sum_{l=0}^{l=N-1}(2 l+1)=N^{2}$ states with this energy. This $N^{2}$-fold degeneracy is larger than the $2 l+1$-fold degeneracy required by rotational
invariance of the hamiltonian. If we believe the converse, that degeneracy implies symmetry, then we might be led to expect that the hydrogen atom exhibits more symmetry than meets the eye.

In fact this symmetry, called a dynamical symmetry [2], exists and is related to a constant of motion that is peculiar to $1 / r^{2}$ force laws. This constant of motion is known as the Laplace-RungeLenz vector. It is a constant of unperturbed planetary motion, for which the force law has the form $\frac{d \mathbf{p}}{d t}=-K \frac{\mathbf{r}}{r^{3}}$, where $K=G M m, G$ is the universal gravitational constant, $M$ and $m$ are the two attracting masses, and $\mathbf{r}=x \hat{\mathbf{i}}+y \hat{\mathbf{j}}+z \hat{\mathbf{k}}$. The time derivative of the vector $\mathbf{p} \times \mathbf{L}$ is

$$
\begin{array}{rlcc}
\frac{d}{d t}(\mathbf{p} \times \mathbf{L}) & = & \frac{d \mathbf{p}}{d t} \times \mathbf{L} & +  \tag{16.23}\\
\mathbf{p} \times \frac{d \mathbf{L}}{d t} \\
& = & -K \frac{\mathbf{r}}{r^{3}} \times(\mathbf{r} \times \mathbf{m} \dot{\mathbf{r}}) & + \\
\downarrow & 0 \\
& = & -m K \frac{\mathbf{r}(\mathbf{r} \cdot \dot{\mathbf{r}})-\dot{\mathbf{r}}(\mathbf{r} \cdot \mathbf{r})}{r^{3}} & = \\
m K \frac{d}{d t}\left(\frac{\mathbf{r}}{r}\right)
\end{array}
$$

In going from the first line in Equ. (16.23) to the second, we use the fact that $\mathbf{L}$ is a constant of motion in any spherically symmetric potential. We also use the force law for a $1 / r$ potential. In going from the second line to the third, we express the cross product $\mathbf{r} \times \mathbf{L}$ in terms of (generally) nonparallel vectors $\mathbf{r}$ and $\dot{\mathbf{r}}$. We also use an identity for $\frac{d}{d t} \frac{\mathbf{r}}{r}$ (cf. Problem ?.?). The result is that the Laplace-Runge-Lenz vector $\mathbf{M}$ is a constant of motion: $d \mathbf{M} / d t=0$, where

$$
\begin{equation*}
\mathbf{M}=\frac{\mathbf{p} \times \mathbf{L}}{m}-K \frac{\mathbf{r}}{r} \tag{16.24}
\end{equation*}
$$

In the transition from classical to quantum mechanics the operator obtained from the classical operator in Equ. (16.25) is not hermitian. Pauli [3] symmetrized it properly, defining the hermitian quauntum mechanical operator

$$
\begin{equation*}
\hat{\mathbf{M}}=\frac{\hat{\mathbf{p}} \times \hat{\mathbf{L}}-\hat{\mathbf{L}} \times \hat{\mathbf{p}}}{2 m}-K \frac{\hat{\mathbf{r}}}{r} \tag{16.25}
\end{equation*}
$$

We will hence dispense with the ^over operators, in part to simplify notation, in part to prevent uncertainties in interpretation of the operator $\mathbf{r}$.

The hermitian operator $\mathbf{M}$ in Equ. (16.25) is a constant of motion, as it commutes with the nonrelativistic hamiltonian: $[H, \mathbf{M}]=0$. The six operators $L_{i}, M_{j}$ obey the following commutation relations

$$
\begin{align*}
{\left[L_{i}, L_{j}\right] } & =i \hbar \epsilon_{i j k} L_{k} \\
{\left[L_{i}, M_{j}\right] } & =i \hbar \epsilon_{i j k} M_{k}  \tag{16.26}\\
{\left[M_{i}, M_{j}\right] } & =\left(-\frac{2 H}{m}\right) i \hbar \epsilon_{i j k} L_{k}
\end{align*}
$$

These are the commutation relations for the Lie algebra of the group $S O(4)$ for bound states $(E<0)$ or $S O(3,1)$ for excited states $(E>0)$. The operators $\mathbf{L}$ and $\mathbf{M}$ also obey

$$
\begin{align*}
\mathbf{L} \cdot \mathbf{M}=\mathbf{M} \cdot \mathbf{L} & =0 \\
\mathbf{M} \cdot \mathbf{M} & =\frac{2 H}{m}\left(\mathbf{L} \cdot \mathbf{L}+\hbar^{2}\right)+K^{2} \tag{16.27}
\end{align*}
$$

In order to simplify the discussion to follow, and make this discussion as independent of the principal quantum number $N$ as possible, we renormalize the Laplace-Runge-Lenz vector by a scale
factor as follows: $\mathbf{M}^{\prime}=\left(-\frac{m}{2 H}\right)^{1 / 2} \mathbf{M}$. (For $E>0$ change $-\rightarrow+$ and $S O(4) \rightarrow S O(3,1)$.) The commutation relations of these operators are now

$$
\begin{align*}
& {\left[L_{i}, L_{j}\right] }=i \hbar \epsilon_{i j k} \\
& {\left[\begin{array}{ll} 
\\
{\left[L_{i}, M_{j}^{\prime}\right]} & =i \hbar \epsilon_{i j k} \\
M_{k}^{\prime} \\
{\left[M_{i}^{\prime}, M_{j}^{\prime}\right]} & =i \hbar \epsilon_{i j k}
\end{array} L_{k}\right.} \tag{16.28}
\end{align*}
$$

The Lie algebra $s o(4)$ is the direct sum of two Lie algebras of type so(3) (cf. Fig. ?.?). It is useful to introduce two vector operators $\mathbf{A}$ and $\mathbf{B}$ as follows

$$
\begin{align*}
& \mathbf{A}=\frac{1}{2}\left(\mathbf{L}+\mathbf{M}^{\prime}\right) \\
& \mathbf{B}=\frac{1}{2}\left(\mathbf{L}-\mathbf{M}^{\prime}\right) \tag{16.29}
\end{align*}
$$

The operators A and B have angular momentum commutation relations. Further, they mutually commute. Finally, their squares have the same spectrum (cf. Problem ?.?).

It is useful at this point to introduce the Schwinger representation for the angular momentum operators $\mathbf{A}$ in terms of two independent boson modes: $A_{3}=\frac{\hbar}{2}\left(a_{1}^{\dagger} a_{1}-a_{2}^{\dagger} a_{2}\right), A_{+}=\hbar a_{1}^{\dagger} a_{2}, A_{-}=$ $\hbar a_{2}^{\dagger} a_{1}$. A similar representation of the angular momentum operators $\mathbf{B}$ in terms of two independent boson operators $b_{1}, b_{2}$ and their adjoints is also introduced.

Basis states for a representation of the algebra spanned by the operators $\mathbf{A}$ have the form $\left|p_{1}, p_{2}\right\rangle$, with $p_{1}+p_{2}=2 j_{a}$ constant and $p_{1}-p_{2}=m_{a}$. The $2 j_{a}+1$ basis states correspond to $p_{1}=2 j_{a}, p_{2}=0 ; p_{1}=2 j_{a}-1, p_{2}=1$; etc. For $\mathbf{B}$ the basis states are $\left|q_{1}, q_{2}\right\rangle$, with $q_{1}+q_{2}=2 j_{b}$ constant and $q_{1}-q_{2}=m_{b}$. The invariant operators are $\mathbf{A} \cdot \mathbf{A}=j_{a}\left(j_{a}+1\right)$ and $\mathbf{B} \cdot \mathbf{B}=j_{b}\left(j_{b}+1\right)$. Since $\mathbf{A} \cdot \mathbf{A}=\mathbf{B} \cdot \mathbf{B}$ (cf. Problem ?.?) $j_{a}=j_{b}$ and the set of states related by the shift operators is $(2 j+1)^{2}$ fold degenerate, where $2 j+1=N=n+l+1$.

States with good $l$ and $m$ quantum numbers can be constructed from these states using ClebschGordan coefficients:

$$
\left|\begin{array}{c}
l  \tag{16.30}\\
m
\end{array}\right\rangle=\left|\begin{array}{cc}
j / 2 & j / 2 \\
m_{a} & m_{b}
\end{array}\right\rangle\left\langle\left.\begin{array}{ll}
j / 2 & j / 2 \\
m_{a} & m_{b}
\end{array} \right\rvert\, \begin{array}{c}
l \\
m
\end{array}\right\rangle
$$

The action of the Laplace-Runge-Lenz shift operators on these states, and the spherical harmonics, is determined in a straightforward way. For example, neglecting factors of $\hbar / i, M_{+}^{\prime}=A_{+}-B_{+}=$ $a_{1}^{\dagger} a_{2}-b_{1}^{\dagger} b_{2}$, so that

$$
\begin{align*}
M_{+}^{\prime} Y_{m}^{l}=\langle\theta \phi| & \left(\begin{array}{cc}
j / 2 & j / 2 \\
m_{a}+1 & m_{b}
\end{array}\right\rangle\left\langle\left.\begin{array}{ccc}
j / 2 & j / 2 \\
m_{a} & m_{b}
\end{array} \right\rvert\, \begin{array}{c}
l \\
m
\end{array}\right\rangle \times \sqrt{\left(j / 2-m_{a}\right)\left(j / 2+m_{a}+1\right)}- \\
& \left.\left|\begin{array}{cc}
j / 2 & j / 2 \\
m_{a} & m_{b}+1
\end{array}\right\rangle\left\langle\left.\begin{array}{ccc}
j / 2 & j / 2 \\
m_{a} & m_{b}
\end{array} \right\rvert\, \begin{array}{c}
l \\
m
\end{array}\right\rangle \times \sqrt{\left(j / 2-m_{b}\right)\left(j / 2+m_{b}+1\right)}\right) \tag{16.31}
\end{align*}
$$

In general, the Laplace-Runge-Lenz operators shift the values of $l$ and $m$ by $\pm 1$ or 0 , while the angular momentum shift operators change only $m$ by $\pm 1$. However, for certain stretched values of the Clebsch-Gordan coefficients, the Laplace-Runge-Lenz vectors act more simply, for example [5]

$$
\begin{align*}
& M_{z}^{\prime}\left|N \begin{array}{c}
\stackrel{l}{l}\rangle
\end{array}\right\rangle \quad D_{1}\left|N^{l+1} \begin{array}{c}
l+ \\
\pm l
\end{array}\right\rangle \quad D_{1}=\frac{1}{N} \sqrt{\frac{N^{2}-(l+1)^{2}}{2 l+3}} \\
& M_{ \pm}^{\prime}\left|\begin{array}{c}
N \\
\pm l
\end{array}\right\rangle= \pm D_{2}\left|N \begin{array}{c}
l+1 \\
\pm(l+1)
\end{array}\right\rangle \quad D_{2}=\frac{1}{N} \sqrt{\frac{2 l+2}{2 l+3}\left[N^{2}-(l+1)^{2}\right]} \tag{16.32}
\end{align*}
$$

### 16.7 Relation With Dynamics in Four Dimensions

The operators $\mathbf{L}$ and $\mathbf{M}^{\prime}$ are infinitesimal generators for the orthogonal group $S O(4)$. The relation between motion in the presence of a Coulomb or gravitational potential and motion in four (mathematical) dimensions was clarified by Fock [9]. Motion of a particle in a $1 / r$ potential is equivalent to motion of a free particle in the sphere $S^{3} \subset R^{4}$.

It is useful first to establish an orthogonal coordinate system in $R^{3}$. It is natural to do this in terms of the constant physical vectors that are available. These include the vectors $\mathbf{L}$ and $\mathbf{M}$. Their cross product $\mathbf{W}=\mathbf{L} \times \mathbf{M}$ is orthogonal to both and also a constant of motion. These vectors obey:

$$
\begin{array}{rlrl}
\mathbf{L} & =\mathbf{r} \times \mathbf{p} & \mathbf{L} \cdot \mathbf{L} & =L^{2} \\
\mathbf{M} & =\frac{\mathbf{p} \times \mathbf{L}}{m}-K \frac{\mathbf{r}}{r} & \mathbf{M} \cdot \mathbf{M} & =M^{2}=\frac{2 E}{m} L^{2}+K^{2}  \tag{16.33}\\
\mathbf{W} & =\frac{\mathbf{p}}{m} L^{2}-K \frac{\mathbf{L}^{2} \times \mathbf{r}}{r} & \mathbf{W} \cdot \mathbf{W} & =L^{2} M^{2}
\end{array}
$$

The particle moves in a plane perpendicular to the angular momentum vector $\mathbf{L}$, since $\mathbf{r} \cdot \mathbf{L}=\mathbf{0}$. The momentum vector moves in the same plane, since $\mathbf{p} \cdot \mathbf{L}=\mathbf{0}$. While $\mathbf{r}$ moves in an ellipse, the momentum vector moves on a circle. For simplicity we choose the $z$ axis in the direction of $\mathbf{L}$ and the $x$ - and $y$-axes in the directions of $\mathbf{M}$ and $\mathbf{W}$. In this coordinate system $p_{z}=0$, $p_{x}=\mathbf{p} \cdot \mathbf{M} / \sqrt{\mathbf{M} \cdot \mathbf{M}}$ and $p_{y}=\mathbf{p} \cdot \mathbf{W} / \sqrt{\mathbf{W} \cdot \mathbf{W}}$. The two nonzero components of the momentum vector are not independent, but obey the constraint

$$
\begin{equation*}
p_{x}^{2}+\left(p_{y}-\frac{m M}{L}\right)^{2}=\left(\frac{m K}{L}\right)^{2} \tag{16.34}
\end{equation*}
$$

This is the equation of a circle in the plane containing the motion. As the particle moves in the plane of motion on an elliptical orbit with one focus at the source, its momentum moves in the same plane on a circular orbit (radius $m K / L$ ) with the center displaced from the origin by $m M / L$.

The circle in $R^{3}$ is lifted to a circle in $S^{3} \subset R^{4}$ by a projective transformation. We extend coordinates from $R^{3}$ to $R^{4}$ as follows:

$$
\begin{array}{ccc}
(x, y, z) \in R^{3} & \rightarrow & (w, x, y, z) \in R^{4} \\
\left(p_{x}, p_{y}, p_{z}\right) \in R^{3} & \rightarrow & \left(p_{w}, p_{x}, p_{y}, p_{z}\right) \in R^{4} \tag{16.35}
\end{array}
$$

With $p_{0}=\sqrt{-2 E / m}$, define the unit vector $\hat{\mathbf{u}} \in S^{3} \subset R^{4}$ by the projective transformation

$$
\begin{equation*}
\hat{\mathbf{u}}=\frac{\mathbf{p} \cdot \mathbf{p}-p_{0}^{2}}{\mathbf{p} \cdot \mathbf{p}+p_{0}^{2}} \hat{\mathbf{w}}+\frac{2 p_{0}}{\mathbf{p} \cdot \mathbf{p}+p_{0}^{2}} \mathbf{p} \tag{16.36}
\end{equation*}
$$

Here $\hat{\mathbf{w}}$ is a unit vector in $R^{4}$ that is orthogonal to all vectors in the physical space $R^{3}$. The transformation in Eq.(16.36) is a stereographic projection. It is invertible and preserves angles
(conformal). It is a simple matter to check that $\hat{\mathbf{u}}$ is a unit vector. The circular trajectory in $R^{3}$ Eq.(16.34) lifts to a circle in $S^{3}$. Reversibly, circles in $S^{3}$ project down to circles in the physical $R^{3}$ space under the reverse transformation.

Rotations in $S O(4)$ rigidly rotate the sphere $S^{3}$ into itself. They rotate circles into circles, which then project down to circular momentum trajectories in the physical space $R^{3}$ :

$$
\begin{equation*}
\text { circle in } R^{3} \xrightarrow{T} \text { circle in } S^{3} \xrightarrow{S O(4)} \text { circle in } S^{3} \xrightarrow{T^{-1}} \text { circle in } R^{3} \tag{16.37}
\end{equation*}
$$

The subgroup $S O(3)$ of rotations around the $\hat{\mathbf{w}}$ axis acts only the the physical space $R^{3}$. In this subgroup, the subgroup $S O(2)$ of rotations around the $z$ axis leaves $\mathbf{L}$ fixed and simply rotates $\mathbf{M}$ in the plane of motion. The coset representatives $S O(3) / S O(2)$ act to reorient the plane of motion by rotating the angular momentum vector $\mathbf{L}$ while keeping the magnitude of $\mathbf{M}$ fixed. Rotations in the coset $S O(4) / S O(3)$ act to change the lengths of both $\mathbf{L}$ and $\mathbf{M}$. All group operations in $S O(4)$ keep $p_{0}$ fixed. In this way the group $S O(4)$ maps states with principal quantum number $N$ into (linear combinations of) states with the same principal quantum number $N$. In short, $S O(4)$ acts on the bound hydrogen atom states through unitary irreducible representations of dimension $N^{2}=(n+l+1)^{2}$.

### 16.8 DeSitter Symmetry $S O(4,1)$

The dynamical symmetry group $S O(4)$ that rotates bound states to bound states does not change their energy; the dynamical symmetry group $S O(3,1)$ that rotates scattering states to scattering states does not change their energy either. It would be nice to find a set of transformations that rescales the energy. If such a group could be found, it would be possible, for example, to map the $1 s$ ground state into any other bounds state. Such a group exists: it is the deSitter group $S O(4,1)$.

We begin with a group that preserves inner products in some $N$-dimensional linear vector space: $\mathbf{x}^{\prime}=M \mathbf{x}$, with $M$ a transformation in the group and the inner product defined by $(\mathbf{x}, \mathbf{x})_{N}=\mathbf{x}^{t} \mathbf{g} \mathbf{x}=$ $x_{i} g_{i j} x_{j}$. As always, the metric-preserving condition leads to $M^{t} G M=G$.

It is useful to define a new $N$-vector $\mathbf{y}$ as a scaled version of the original vector: $\mathbf{y}=\lambda \mathbf{x}$. We define $z_{1}=\lambda$ and introduce a second coordinate $z_{2}=\lambda(\mathbf{x}, \mathbf{x})_{N}$. With these definitions we find the conformal condition

$$
\begin{equation*}
(\mathbf{y}, \mathbf{y})_{N}-z_{1} z_{2}=(\lambda \mathbf{x}, \lambda \mathbf{x})_{N}-\lambda\left[\lambda(\lambda \mathbf{x}, \lambda \mathbf{x})_{N}\right]=0 \tag{16.38}
\end{equation*}
$$

The conformal condition defines an inner product in the $N+2$ dimensional linear vector space that is non diagonal in the coordinates $\mathbf{y}, z_{1}, z_{2}$ but diagonal in the coordinates $\mathbf{y}, y_{N+1}, y_{N+2}$, with $y_{N+1}=\frac{1}{2}\left(z_{1}+z_{2}\right)$ and $y_{N+2}=\frac{1}{2}\left(z_{1}-z_{2}\right)$ :

the conformal conditon Eq.(16.38) defines a cone in the enlarged $N+2$ dimensional space. If the group that preserves the metric $G$ in $R^{N}$ is $S O(p, q)$ the group that preserves the metric in $R^{N+2}$ is $S O(p+1, q+1)$. We seek to construct a spherical or hyperbolic slice of this cone.

The connection with the Kepler problem is made as follows. The momenta $\mathbf{p}$ are lifted to projective transformation to the coordinates of a sphere $S^{3} \subset R^{4}(E<0)$ or a two-sheeted hyperboloid
$H^{3} \subset R^{4}(E>0)$ by the following projective transformations:

$$
\begin{array}{ll}
\hat{\mathbf{u}}=\frac{\frac{1}{2}\left(p_{0}^{2}-\mathbf{p} \cdot \mathbf{p}\right)}{\frac{1}{2}\left(p_{0}^{2}-\mathbf{p} \cdot \mathbf{p}\right)} \mathbf{w}+\frac{p_{0} \mathbf{p}}{\frac{1}{2}\left(p_{0}^{2}-\mathbf{p} \cdot \mathbf{p}\right)} & E<0  \tag{16.40}\\
\hat{\mathbf{u}}=\frac{\frac{1}{2}\left(p_{0}^{2}+\mathbf{p} \cdot \mathbf{p}\right)}{\frac{1}{2}\left(p_{0}^{2}-\mathbf{p} \cdot \mathbf{p}\right)} \mathbf{w}+\frac{p_{0} \mathbf{p}}{\frac{1}{2}\left(p_{0}^{2}-\mathbf{p} \cdot \mathbf{p}\right)} & E>0
\end{array}
$$

For the 4 -vectors $\mathbf{u}$ the metric $G$ that appears in Eq.(16.39) is determined from the denominators in Eq.(16.40):

$$
\mathbf{u}^{t} G \mathbf{u}=u_{0}^{2} \pm \sum_{i=1}^{3} u_{i}^{2} \quad \begin{array}{lll}
+1 & \text { for } \quad E<0  \tag{16.41}\\
-1 & \text { for } \quad E>0
\end{array}
$$

The algebraic surfaces on which the projective vector $\mathbf{u}$ lies is defined by the condition $\mathbf{u}^{t} G \mathbf{u}=1$.
The connection with the conformal transformations introduced above is as follows. The group that leaves invariant the conformal metric diag $\left(1, \pm I_{3},-1,+1\right)$ is $S O(5,1)$ for $E<0$ and $S O(2,4)$ for $E>0$. On the surfaces (sphere, hyperboloid) the condition $\mathbf{u}^{t} G \mathbf{u}=1$ is satisfied, so that $z_{1}=z_{2}$ and $y_{4}=\lambda$ and $y_{5}=0$ (the six coordinates are labeled $\left(y_{0}, \mathbf{y}=\lambda \mathbf{u}, y_{4}=\frac{1}{2}\left(z_{1}+z_{2}\right), y_{5}=\frac{1}{2}\left(z_{1}-z_{2}\right)\right)$. Transformations that map the algebraic surface to itself must map $y_{5}=0$ to $y_{5}=0$. It is a simple matter to verify that this is the matrix subgroup of the $6 \times 6$ matrix group $S O(5,1)$ or $S O(2,4)$ of the form $\left[\begin{array}{cc}M & 0 \\ 0 & 1\end{array}\right]$, with $M$ a $5 \times 5$ matrix that preserves the metric $\operatorname{diag}\left(1, \pm I_{3},-1\right)$ in $R^{5}$. This is $S O(4,1)$ for $E<0$ and $S O(1,4)$ for $E>0$.

It remains to show that this group maps these algebraic surfaces into themselves. To this end we write the linear transformation in $R^{5}$ as follows

$$
\left[\begin{array}{c}
\lambda \mathbf{u}  \tag{16.42}\\
\lambda
\end{array}\right]^{\prime}=\left[\begin{array}{ll}
A & B \\
C & D
\end{array}\right]\left[\begin{array}{c}
\lambda \mathbf{u} \\
\lambda
\end{array}\right]
$$

where $A$ is a $4 \times 4$ matrix, etc. From this we determine

$$
\begin{equation*}
\mathbf{u}^{\prime}=\frac{A(\lambda \mathbf{u})+B \lambda}{C(\lambda \mathbf{u})+D \lambda} \tag{16.43}
\end{equation*}
$$

The inner product of $\mathbf{u}^{\prime}$ with itself satisfies

$$
\begin{equation*}
\left(\mathbf{u}^{\prime}\right)^{t} G \mathbf{u}^{\prime}-1=\frac{(A \lambda \mathbf{u}+B \lambda)^{t} G(A \lambda \mathbf{u}+B \lambda)-(C \lambda \mathbf{u}+D \lambda)^{t}(C \lambda \mathbf{u}+D \lambda)}{(C \lambda \mathbf{u}+D \lambda)^{t}(C \lambda \mathbf{u}+D \lambda)} \tag{16.44}
\end{equation*}
$$

By using the relations among the submatrices required by the metric preserving condition (e.g., $A^{t} G A-C^{T} C=G$, etc.) it is a simple matter to show that this reduces to

$$
\begin{equation*}
\left(\mathbf{u}^{\prime}, \mathbf{u}^{\prime}\right)_{N}-1=\frac{(\mathbf{u}, \mathbf{u})_{N}-1}{(C \mathbf{u}+D)^{t}(C \mathbf{u}+D)} \tag{16.45}
\end{equation*}
$$

In short, the algebraic surface is invariant under this transformation group.
Remark: The subgroup $S O(4)$ rigidly rotates the sphere $S^{3} \subset R^{4}$ into itself while the subgroup $S O(3,1)$ "rigidly rotates" the hyperboloid into itself. In the latter case this is less intuitive. This means that the coordinates of the hyperboloid are mapped into themselves by a linear transformation in $R^{4}$. The group $S O(4,1)$ maps coordinates in these spaces to themselves through a nonlinear
transformation in $R^{4}$ : in this case a simple projective transformation. It is a linear transformation in $R^{5}$.

The infinitesimal generators of this nonlinear transformation are constructed as follows [?, ?]. For $E<0$ introduce a 4 -vector $u$ as usual $\left(u_{0} \rightarrow u_{4}\right)$

$$
\begin{align*}
\mathbf{u} & =2 p_{4}\left(\mathbf{p} \cdot \mathbf{p}+p_{4}^{2}\right)^{-1} \mathbf{p}  \tag{16.46}\\
u_{4} & =\left(\mathbf{p} \cdot \mathbf{p}-p_{4}^{2}\right)\left(\mathbf{p} \cdot \mathbf{p}+p_{4}^{2}\right)^{-1}
\end{align*}
$$

Define the 4 -vector B in terms of the 4 -vector $u$ and the angular momentum vector $\mathbf{L}$ and the scaled (by $1 / \sqrt{2 m|E|}$ ) Runge-Lenz vector $\mathbf{M}^{\prime}$ as follows:

$$
\begin{aligned}
\mathbf{B} & =\mathbf{M}^{\prime} u_{4}+\mathbf{L} \times \mathbf{u}-\frac{3}{2} i \mathbf{u}
\end{aligned}=\frac{i}{2}\left[\mathbf{u}, \mathbf{L}^{2}+\mathbf{M}^{\prime 2}\right] .
$$

The operators $L_{i}, M_{i}^{\prime}$, and $B_{\mu}$ are the infinitesimal generators of $S O(4,1)$ as follows, for $E<0$.

$$
\left[\begin{array}{cccc|c}
0 & L_{3} & -L_{2} & M_{1} & B_{1} \\
-L_{3} & 0 & L_{1} & M_{2} & B_{2} \\
L_{2} & -L_{1} & 0 & M_{3} & B_{3} \\
-M_{1} & -M_{2} & -M_{3} & 0 & B_{4} \\
\hline B_{1} & B_{2} & B_{3} & B_{4} & 0
\end{array}\right] \begin{aligned}
& + \\
& + \\
& + \\
& + \\
& -
\end{aligned}
$$

### 16.9 Conformal Symmetry $S O(4,2)$

The largest set of transformations that leave the states of the hydrogen atom invariant, in some sense, is the conformal group $S O(4,2)$. Several different ways have been developed to prove this point. We review three of these viewpoints here, in order of increasing power.

### 16.9.1 Algebraic

The algebra of the dynamical symmetry group has infinitesimal generators $\mathbf{L}$ and $\mathbf{M}^{\prime}$. Their linear combinations given two sets of vector operators $\mathbf{A}$ and $\mathbf{B}$ that mutually commute and have angular momentum commutation relations on bound states. It is possible to represent these operators using the boson representation. That is, for the operators $\mathbf{A}$ we introduce annihilation and creation operators $a_{i}, a_{j}^{\dagger}$ for two independent modes, and similarly we introduce operators $b_{i}, b_{j}^{\dagger}$ to describe B. Basis states on which these operators act have the form $\left|m_{1}, m_{2} ; n_{1}, n_{2}\right\rangle$ where, for example

$$
\begin{aligned}
a_{1}^{\dagger} a_{2}\left|m_{1}, m_{2} ; n_{1}, n_{2}\right\rangle & =\left|m_{1}+1, m_{2}-1 ; n_{1} n_{2}\right\rangle \sqrt{m_{1}+1} \sqrt{m_{2}} \\
b_{1}^{\dagger} b_{1}\left|m_{1}, m_{2} ; n_{1}, n_{2}\right\rangle & =\left|m_{1}, m_{2} ; n_{1} n_{2}\right\rangle\left(n_{1}\right)^{2}
\end{aligned}
$$

The orthogonality of $\mathbf{L}$ and $\mathbf{M}$ leads to the orthogonality of $\mathbf{A}$ and $\mathbf{B}$, and this leads directly to the condition $j_{a}=j_{b}$, where $j_{a}=\frac{1}{2}\left(m_{1}+m_{2}\right)$ and $j_{b}=\frac{1}{2}\left(n_{1}+n_{2}\right)$.

From the previous section we know there is a group that maps bound states into (linear combinations of) bound states. We determine an algebra of operators that performs the same function on bound states as follows. Operators that change the principle quantum number $N=2 j_{a}+1=$ $2 j_{b}+1=\left(j_{a}+j_{b}\right)+1$ must change $j_{a}=j_{b}$. Operators that change $j_{a}$ have the form $a_{i}^{\dagger}$ or $a_{i}^{\dagger} a_{j}^{\dagger}$, but they do not simultaneously change $j_{b}$. Only operators that simultaneously add or subtract one excitation to the subsystems $A$ and $B$ simultaneously maintain the constraint $j_{a}=j_{b}$. The largest
set of operators bilinear in the boson operators that map hydrogen atom bound states to bound states consists of the operators

| Operators | $a_{i}^{\dagger} a_{j}$ | $b_{i}^{\dagger} b_{j}$ | $a_{i}^{\dagger} b_{j}^{\dagger}$ | $a_{i} b_{j}$ |
| :--- | :---: | :---: | :---: | :---: |
| Subalgebra | $u(2)$ | $u(2)$ |  |  |
| Number | 4 | 4 | 4 | 4 |

What is this algebra? Among these 16 operators, the maximal number of mutually commuting operators that can be found is four. These are conveniently chosen as the number operators for the four boson modes: $\left(H_{1}, H_{2}, H_{3}, H_{4}\right)=\left(a_{1}^{\dagger} a_{1}, a_{2}^{\dagger} a_{2}, b_{1}^{\dagger} b_{1}, b_{2}^{\dagger} b_{2}\right)$. The remaining twelve operators have eigenoperator commutation relations with this set:

$$
\begin{array}{cccccc}
a_{1}^{\dagger} a_{2} & (+1,-1,0,0) & a_{1}^{\dagger} b_{1}^{\dagger} & (+1,0,+1,0) & a_{1} b_{1} & (-1,0,-1,0)  \tag{16.48}\\
a_{2}^{\dagger} a_{1} & (-1,+1,0,0) & a_{1}^{\dagger} b_{2}^{\dagger} & (+1,0,0,+1) & a_{1} b_{2} & (-1,0,0,-1) \\
b_{1}^{\dagger} b_{2} & (0,0+1,-1) & a_{2}^{\dagger} b_{1}^{\dagger} & (0,+1,+1,0) & a_{2} b_{1} & (0,-1,-1,0) \\
b_{2}^{\dagger} b_{1} & (0,0,-1,+1) & a_{2}^{\dagger} b_{2}^{\dagger} & (0,+1,0,+1) & a_{2} b_{2} & (0,-1,0,-1)
\end{array}
$$

All these roots have equal length, and inner products among these roots are all $\pm \frac{1}{2}$ or 0 . The operator

$$
\left(a_{1}^{\dagger} a_{1}+a_{2}^{\dagger} a_{2}\right)-\left(b_{1}^{\dagger} b_{1}+b_{2}^{\dagger} b_{2}\right)
$$

commutes with all operators in this set. It is a constant of motion, and in fact vanishes on all hydrogen atom bound states. As a result the algebra is the direct sum of an abelian invariant subalgebra spanned by this operator, and a rank-three simple Lie algebra all of whose roots have equal lengths and are either orthogonal or make angles of $\frac{\pi}{4}$ or $\frac{3 \pi}{4}$ radians with each other. The algebra is uniquely a real form of $A_{3}=D_{3}$.

Which real form? It is possible to form a number of subalgebras of type $A_{1}$ from these operators:

$$
\begin{array}{cccc}
a_{1}^{\dagger} a_{2} & a_{2}^{\dagger} a_{1} & \frac{1}{2}\left(a_{1}^{\dagger} a_{1}-a_{2}^{\dagger} a_{2}\right) & s u(2) \\
b_{1}^{\dagger} b_{2} & b_{2}^{\dagger} b_{1} & \frac{1}{2}\left(b_{1}^{\dagger} b_{1}-b_{2}^{\dagger} b_{2}\right) & s u(2) \\
a_{i}^{\dagger} b_{j}^{\dagger} & a_{i} b_{j} & \frac{1}{2}\left(a_{i}^{\dagger} a_{i}+b_{j}^{\dagger} b_{j}\right) & s u(1,1)
\end{array}
$$

The first two are compact, the last four are not compact. The maximal compact subalgebra is spanned by the two compact subalgebras together with the diagonal operator $a_{1}^{\dagger} a_{1}+a_{2}^{\dagger} a_{2}+b_{1}^{\dagger} b_{1}+b_{2}^{\dagger} b_{2}$. This is the algebra $s o(4)+s o(2)$. The fifteen dimensional Lie algebra that maps bound states to bound states is therefore $s o(4,2)=s u(2,2)$. This is the conformal algebra.

### 16.9.2 Dynamical

Although the classical Kepler problem is analytically solvable, analyticity disappears under perturbation. In this case classical orbits must be computed numerically. At points of very close approach the velocity of the particles increases greatly, so it is prudent to slow down the integration time step to preserve accuracy. This procedure has been implemented formally through a canonical transformation $[10,11]$, and is now widely known as the Kustaanheimo-Stiefel transformation. Under this transformation time is stretched out for small $R$. In addition the (relative) coordinates are projected from $R^{3}$ to a fictitious space $R^{4}$. Under this transformation, and a constraint, the Kepler hamiltonian is transformed into a four dimensional harmonic oscillator hamiltonian.

Coordinates $\left(q_{1}, q_{2}, q_{3}, q_{4}\right)$ in the fictitions space $R^{4}$ are related to coordinates ( $Q_{1}, Q_{2}, Q_{3}$ ) in the real space by the $4 \times 4$ transformation

$$
\left[\begin{array}{l}
Q_{1}  \tag{16.49}\\
Q_{2} \\
Q_{3} \\
Q_{4}
\end{array}\right]=M_{K S}\left[\begin{array}{l}
q_{1} \\
q_{2} \\
q_{3} \\
q_{4}
\end{array}\right]=\left[\begin{array}{cccc}
q_{1} & -q_{2} & -q_{3} & q_{4} \\
q_{2} & q_{1} & -q_{4} & -q_{3} \\
q_{3} & q_{4} & q_{1} & q_{2} \\
q_{4} & -q_{3} & q_{2} & -q_{1}
\end{array}\right]\left[\begin{array}{l}
q_{1} \\
q_{2} \\
q_{3} \\
q_{4}
\end{array}\right]
$$

The transformation is constructed so that the "fourth" real coordinate $Q_{4}$ is identically zero. This transformation is invertible provided $q_{1}^{2}+q_{2}^{2}+q_{3}^{2}+q_{4}^{2} \neq 0$. The distance $R=\sqrt{Q_{1}^{2}+Q_{2}^{2}+Q_{3}^{2}}$ in $R^{3}$ and the distance $q=\sqrt{q_{1}^{2}+q_{2}^{2}+q_{3}^{2}+q_{4}^{2}}$ in $R^{4}$ are related by: $R=q^{2}$.

The other half of the canonical transformation, involving the momenta in the real and fictitious space, is

$$
\left(P_{1}, P_{2}, P_{3}, P_{4}\right)^{t}=\frac{1}{2 R} M_{K S}\left(p_{1}, p_{2}, p_{3}, p_{4}\right)^{t}
$$

A constraint condition must be applied to force $P_{4}=0$. This condition is

$$
\begin{equation*}
\zeta=-2 R P_{4}=\left(q_{1} p_{4}-q_{4} p_{1}\right)+\left(q_{3} p_{2}-q_{2} p_{3}\right)=0 \tag{16.50}
\end{equation*}
$$

With this constraint we find $P^{2}=P_{1}^{2}+P_{2}^{2}+P_{3}^{2}=\frac{1}{4 R} p^{2}-\frac{\zeta^{2}}{4 R^{2}} \rightarrow \frac{1}{4 R}\left(p_{1}^{2}+p_{2}^{2}+p_{3}^{2}+p_{4}^{2}\right)$. With these transformations the hamiltonian in the real space can be transformed to a hamiltonian in the fictitious space by

$$
\begin{equation*}
\frac{P^{2}}{2 m}-\frac{e^{2}}{R}=E \xrightarrow{\times R} \frac{R P^{2}}{2 m}-e^{2}=E R \xrightarrow{K S} \frac{p^{2}}{8 m}-e^{2}=E q^{2} \tag{16.51}
\end{equation*}
$$

This is the hamiltonian for a four-dimensional harmonic oscillator when $E<0$, as easily seen by rearranging the terms

$$
\begin{equation*}
\frac{p^{2}}{2 m}-4 E q^{2}=4 e^{2} \tag{16.52}
\end{equation*}
$$

The angular momentum operators in the real and fictitious spaces are bilinear products of the position and momentum coordinates, as follows:
$\left(Q_{1}, Q_{2}, Q_{3}, Q_{4}\right)\left[\begin{array}{cccc}0 & \theta_{3} & -\theta_{2} & * \\ -\theta_{3} & 0 & \theta_{1} & * \\ \theta_{2} & -\theta_{1} & 0 & * \\ -* & -* & -* & 0\end{array}\right]\left[\begin{array}{c}P_{1} \\ P_{2} \\ P_{3} \\ P_{4}\end{array}\right] \quad \frac{1}{2}\left(q_{1}, q_{2}, q_{3}, q_{4}\right)\left[\begin{array}{cccc}0 & \theta_{3} & -\theta_{2} & \theta_{1} \\ -\theta_{3} & 0 & \theta_{1} & \theta_{2} \\ \theta_{2} & -\theta_{1} & 0 & \theta_{3} \\ -\theta_{1} & -\theta_{2} & -\theta_{3} & 0\end{array}\right]\left[\begin{array}{l}p_{1} \\ p_{2} \\ p_{3} \\ p_{4}\end{array}\right]$
Similar expressions can be given for the Runge-Lenz vector. However, these are quadratic in the position and momentum operators. As a result they must be expressed in matrix form using $8 \times 8$ matrices acting on the vectors ( $q_{1}, q_{2}, q_{3}, q_{4} ; p_{1}, p_{2}, p_{3}, p_{4}$ ) on the left and its transpose on the right [12].

We now ask: what is the largest group of transformations on the coordinates and momenta that:
a. is linear
b. is canonical
c. preserves $\zeta=0$.

We address this question in the usual way. Linear transformations allow us to use matrices. These are $8 \times 8$ matrices acting on the four coordinates and four momenta. Preserving the Poisson brackets requires that the matrices satisfy a symplectic metric-preserving condition: $M^{t} G_{1} M=G_{1}$. Preserving the condition $\zeta=0$ requires these transformations to satisfy another metric-preserving condition: $M^{t} G_{2} M=G_{2}$.

The matrices $G_{i}$ have the form $G_{i}=\left[\begin{array}{cc}0 & M_{i} \\ -M_{i} & 0\end{array}\right]$, where

$$
\begin{array}{ll}
M_{1}=\left[\begin{array}{cccc}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{array}\right] & M_{2}=\left[\begin{array}{cccc}
0 & 0 & 0 & 1 \\
0 & 0 & -1 & 0 \\
0 & 1 & 0 & 0 \\
-1 & 0 & 0 & 0
\end{array}\right]  \tag{16.54}\\
M_{1}^{t}=+M_{1} & G_{1}^{t}=-G_{1}
\end{array}
$$

The metric $G_{1}$ is antisymmetric and the metric $G_{2}$ is symmetric, with signature $(+4,-4)$. The group that preserves the antisymmetric metric is $S p(8 ; R)$ and the group that preserves the symmetric metric is $S O(4,4)$. The group that satisfies both metric-preserving conditions is their intersection:

$$
\begin{equation*}
S p(8 ; R) \cap S O(4,4)=S U(2,2) \simeq S O(4,2) \tag{16.55}
\end{equation*}
$$

The simplest way to see this result is to perform a canonical transformations from coordinates $(q, p)$ to coordinates $(s, r)$ :

$$
\begin{array}{ll}
{\left[\begin{array}{l}
s_{1} \\
r_{4}
\end{array}\right]=\frac{1}{\sqrt{2}}\left[\begin{array}{cc}
1 & 1 \\
-1 & 1
\end{array}\right]\left[\begin{array}{l}
q_{1} \\
p_{4}
\end{array}\right]} & {\left[\begin{array}{l}
s_{2} \\
r_{3}
\end{array}\right]=\frac{1}{\sqrt{2}}\left[\begin{array}{cc}
-1 & 1 \\
-1 & -1
\end{array}\right]\left[\begin{array}{l}
q_{2} \\
p_{3}
\end{array}\right]} \\
{\left[\begin{array}{l}
s_{3} \\
r_{2}
\end{array}\right]=\frac{1}{\sqrt{2}}\left[\begin{array}{cc}
1 & 1 \\
-1 & 1
\end{array}\right]\left[\begin{array}{l}
q_{3} \\
p_{2}
\end{array}\right]} & {\left[\begin{array}{l}
s_{4} \\
r_{1}
\end{array}\right]=\frac{1}{\sqrt{2}}\left[\begin{array}{cc}
-1 & 1 \\
-1 & -1
\end{array}\right]\left[\begin{array}{l}
q_{4} \\
p_{1}
\end{array}\right]} \tag{16.56}
\end{array}
$$

Since the new coordinates are already canonical, only the condition $\zeta=0$ remains to be satisfied. It is a simple matter to verify that

$$
\begin{array}{ll}
z_{1}=\frac{1}{\sqrt{2}}\left(s_{1}+i s_{2}\right) & z_{2}=\frac{1}{\sqrt{2}}\left(r_{1}+i r_{2}\right) \\
z_{3}=\frac{1}{\sqrt{2}}\left(s_{3}+i s_{4}\right) \quad z_{4}=\frac{1}{\sqrt{2}}\left(r_{3}+i r_{4}\right) \tag{16.57}
\end{array} \quad z_{1}^{*} z_{1}-z_{2}^{*} z_{2}+z_{3}^{*} z_{3}-z_{4}^{*} z_{4}=\zeta
$$

The noncompact group $U(2,2)$ preserves the constraint Eq.(16.50).

### 16.9.3 Lie Theory

## XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXBegin here

[13] The generators $\Gamma_{5}, \Gamma_{4}$, and $M_{4}$ of the spectrum generating algebra are constructed from operators $r$ and $d / d r$ that are rotation invariant: that is, they commute with the angular momentum operators $\mathbf{L}=\mathbf{r} \times \mathbf{p}$. It is for this reason they do not change the angular momentum value $l$. These operators do not commute with the Laplace Runge Lenz vector $\mathbf{M}$. In fact, the generators of the spectrum generating algebra depend on the angular momentum values $l$ and the generators of the Laplace-Runge-Lenz vector, as we have used them, depend on the hamiltonian through their normalization.

We can ask if it is possible to construct a set of operators that are independent of the quantum numbers of the hydrogen atom states, that close under commutation, and that have nonzero matrix elements between all the hydrogenic states.

The answer is yes. In fact, a qualified yes. The set of operators that is introduced below has nonzero matrix elements between bound states and bound states, scattering states and scattering states, or states with $E=0$. In other words, all the hydrogenic states belong to one of three distinct repressentations of the algebra and its corresponding group.

The 15 operators that close under commutation can be considered as a pair of 3 -vectors, a 4 -vector, and a five dimensional vector. These operators are

$$
\begin{array}{rlrlrl}
\mathbf{J} & =\mathbf{r} \times \mathbf{p} & & \\
\mathbf{M} & =\frac{1}{m} \mathbf{r}(\mathbf{p} \cdot \mathbf{p})-\mathbf{p}(\mathbf{r} \cdot \mathbf{p})-K \hat{\mathbf{r}} & & \\
\mathbf{A} & =\frac{1}{m} \mathbf{r}(\mathbf{p} \cdot \mathbf{p})-\mathbf{p}(\mathbf{r} \cdot \mathbf{p})+K \hat{\mathbf{r}} & A_{4}=\mathbf{r} \cdot \mathbf{p}+\frac{3}{2} \frac{\hbar}{i} & \\
\Gamma & =r \mathbf{p}+\frac{1}{2} \frac{\hbar}{i} \hat{\mathbf{r}} & \Gamma_{4}=\frac{1}{2}(r \mathbf{p} \cdot \mathbf{p}-r) \quad \Gamma_{5}=\frac{1}{2}(\mathbf{p} \cdot \mathbf{p}+r) \tag{16.58}
\end{array}
$$

N.B. The operator $r \mathbf{p} \cdot \mathbf{p}$ is not hermitian. If you wish to project out the hermitian part of this operator, it is

$$
\begin{aligned}
& r \mathbf{p} \cdot \mathbf{p} \xrightarrow{\text { hermitian }}{ }^{\text {part }} r \mathbf{p} \cdot \mathbf{p}+\frac{\hbar}{i} \hat{\mathbf{r}} \cdot \mathbf{p}-\frac{\hbar^{2}}{r} \\
& \mathbf{L}=\mathbf{r} \times \pi \\
& \mathbf{M}=\frac{\mathbf{p} \times \mathbf{L}-\mathbf{L} \times \mathbf{p}}{2 m}-\frac{e^{2}}{r} \\
& {\left[\begin{array}{cccc|cc}
0 & L_{3} & -L_{2} & M_{1} & ? & \Gamma_{1} \\
-L_{3} & 0 & L_{1} & M_{2} & ? & \Gamma_{2} \\
L_{2} & -L_{1} & 0 & M_{3} & ? & \Gamma_{3} \\
-M_{1} & -M_{2} & -M_{3} & 0 & ? & \Gamma_{4} \\
\hline ? & ? & ? & ? & 0 & \Gamma_{5} \\
\Gamma_{1} & \Gamma_{2} & \Gamma_{3} & \Gamma_{4} & -\Gamma_{5} & 0
\end{array}\right]+} \\
& M_{4}=\mathbf{r} \cdot \mathbf{p}-i \\
& \Gamma_{4}=\frac{1}{2}\left(r \pi^{2}-r\right) \\
& \Gamma_{4}=\frac{1}{2}\left(r \pi^{2}+r\right) \\
& \Theta=r\left(H_{S}-E\right)=\frac{1}{2 m}\left(\Gamma_{5}+\Gamma_{4}\right)-E\left(\Gamma_{5}-\Gamma_{4}\right)-\alpha \\
& M_{4}=\mathbf{r} \cdot \pi-i \\
& \Gamma_{4}=\frac{1}{2}\left(r \pi^{2}-r-\frac{\alpha^{2}}{r}\right) \\
& \Gamma_{4}=\frac{1}{2}\left(r \pi^{2}+r-\frac{\alpha^{2}}{r}\right) \\
& \Theta=r\left\{\left(H_{K G}+\frac{\alpha}{r}\right)^{2}-\left(E+\frac{\alpha}{r}\right)^{2}\right\}=\left(\Gamma_{5}+\Gamma_{4}\right)-\left(E^{2}-m^{2}\right)\left(\Gamma_{5}-\Gamma_{4}\right)-2 \alpha E
\end{aligned}
$$

$$
\begin{aligned}
& M_{4}=\mathbf{r} \cdot \pi-i \\
& \Gamma_{4}=\frac{1}{2}\left(r \pi^{2}-r-\frac{\alpha^{2}}{r}-\frac{i \alpha \mathbf{r} \cdot \alpha}{r^{2}}\right) \\
& \Gamma_{4}=\frac{1}{2}\left(r \pi^{2}+r-\frac{\alpha^{2}}{r}-\frac{i \alpha \mathbf{r} \cdot \alpha}{r^{2}}\right) \\
& \Theta=r\left\{\left(H_{D}+\frac{\alpha}{r}\right)^{2}-\left(E+\frac{\alpha}{r}\right)^{2}\right\}=\left(\Gamma_{5}+\Gamma_{4}\right)-\left(E^{2}-m^{2}\right)\left(\Gamma_{5}-\Gamma_{4}\right)-2 \alpha E \\
& K_{0}=-\frac{d^{2}}{d x^{2}}+\frac{\alpha}{x^{2}}+\frac{x^{2}}{16} \\
& K_{1}=-\frac{d^{2}}{d x^{2}}+\frac{\alpha}{x^{2}}-\frac{x^{2}}{16} \\
& K_{2}=-\frac{i}{2}\left(x \frac{d}{d x}+\frac{1}{2}\right)
\end{aligned}
$$

Cas $=K_{0}^{2}-K_{1}^{2}-K_{2}^{2}=\frac{\alpha}{4}-\frac{3}{16}=(\lambda-1)(\lambda)$

$$
\mathrm{CR}\left[K_{0}, K_{1}\right]=i K_{2},\left[K_{1}, K_{2}\right]=-i K_{0},\left[K_{2}, K_{0}\right]=i K_{1}
$$

### 16.10 Spin Angular Momentum

### 16.11 Spectrum Generating Group

The physics of the hydrogenic problem is determined primarily by the radial equation Equ. (16.9). It is possible to determine solutions of this equation using operaturs that close under commutation. These are the generators of a Lie algebra. The corresponding group is called a spectrum generating group.

To construct a set of operators that close under commutation, we first simplify the radial equation by multiplying on the left by $r$

$$
\begin{equation*}
\left(r D^{2}+\frac{A}{r}+B+C r\right) R(r)=0 \tag{16.59}
\end{equation*}
$$

with $D=d / d r$. The operators $r$ and $D$ behave under commutation like the boson creation and annihilation operators $a^{\dagger}$ and $a$. In fact, the nonzero commutation relations are

$$
\begin{align*}
{[r D, r] } & =+r & {\left[a^{\dagger} a, a^{\dagger}\right] } & =+a^{\dagger} \\
{\left[r D, r D^{2}\right] } & =-r D^{2} & {\left[a^{\dagger} a, a^{\dagger} a a\right] } & =-a^{\dagger} a a  \tag{16.60}\\
{\left[r, r D^{2}\right] } & =-2 r D & {\left[a^{\dagger}, a^{\dagger} a a\right] } & =-2 a^{\dagger} a
\end{align*}
$$

The linear combinations $r D^{2}-r$ and $r D^{2}+r$ are compact and noncompact, respectively. In order to model the differential operator Equ. (16.59) with a set of operators that close under commutation to form a finite-dimensional Lie algebra, we must be careful, as

$$
\begin{aligned}
{\left[r D, \frac{1}{r}\right] } & =-\frac{1}{r} \\
{\left[r D^{2}, \frac{1}{r}\right] } & =\frac{2}{r^{2}}-\frac{1}{r} D
\end{aligned}
$$

We choose as operators in the Lie algebra so(2,1) the three differential operators

$$
\begin{align*}
\Gamma_{5} & =\frac{1}{2}\left(r D^{2}+\frac{a}{r}-r\right) \\
\Gamma_{4} & =\frac{1}{2}\left(r D^{2}+\frac{a}{r}+r\right)  \tag{16.61}\\
M_{4} & =r D
\end{align*}
$$

The Casimir operator for this algebra is $C^{2}=\Gamma_{5}^{2}-\Gamma_{4}^{2}-M_{4}^{2}=a$. The representations of this algebra have been described in Problem ???

The radial equation Equ. (??) is expressed in terms of the three operators as follows ( $a \rightarrow A$ )

$$
\begin{equation*}
\left(\left(\Gamma_{5}+\Gamma_{4}\right)+B+C\left(\Gamma_{5}-\Gamma_{4}\right)\right) R(r)=0 \tag{16.62}
\end{equation*}
$$

Next, we rotate the generators of the algebra according to

$$
e^{\theta M_{4}}\binom{\Gamma_{5}}{\Gamma_{4}} e^{-\theta M_{4}}=\left[\begin{array}{rr}
\cosh \theta & -\sinh \theta  \tag{16.63}\\
-\sinh \theta & \cosh \theta
\end{array}\right]\binom{\Gamma_{5}}{\Gamma_{4}}
$$

When this similarity transformation is applied to Equ.(16.62) we obtain the following result:

$$
\begin{equation*}
\left[\left(e^{-\theta}-C e^{\theta}\right) \Gamma_{5}+\left(e^{-\theta}+C e^{\theta}\right) \Gamma_{4}+B\right] e^{\theta M_{4}} R(r)=0 \tag{16.64}
\end{equation*}
$$

The rotation angle $\theta$ can be chosen to eliminate either the noncompact generator $\Gamma_{4}$ or the compact generator $\Gamma_{5}$, depending on the sign of the parameter $C$.

### 16.11.1 Bound States

If $C<0$ we can choose $e^{-\theta}+C e^{\theta}=0$, so that the resulting equation becomes

$$
\begin{equation*}
\left(-2 \sqrt{-C} \Gamma_{5}+B\right) u(r)=0 \tag{16.65}
\end{equation*}
$$

where $u(r)=e^{\theta M_{4}} R(r)$. If $A$ is the Casimir invariant of this representation of $s u(1,1)$, the spectrum of the compact operator $\Gamma_{5}$ is $N=-\frac{1}{2}+\sqrt{\left(\frac{1}{2}\right)^{2}-A}+1+n, n=0,1,2, \ldots$. Accordingly, the algebraic equation reduces to

$$
\begin{equation*}
(-2 N \sqrt{-C}+B) u(r)=0 \quad \text { Non-Relativistic } \quad E=-\frac{1}{2} m c^{2} \alpha^{2} \frac{1}{(n+j+1)^{2}} \tag{16.66}
\end{equation*}
$$

Solving this equation gives the quantization condition obtained through solution of the radial equation using the standard Frobenius procedure:

$$
\begin{equation*}
j+1+n=\frac{B}{2 \sqrt{-C}} \tag{16.67}
\end{equation*}
$$

The result can be applied either to the Schrödinger equation or to the Klein Gordan equation. In this expression, and an analogous expression below, $j$ is the solution of the quadratic equation $j(j+1)+A=0$ :

$$
\begin{equation*}
j=-\frac{1}{2}+\sqrt{\left(\frac{1}{2}\right)^{2}-A} \tag{16.68}
\end{equation*}
$$

$-\mathrm{N} * * 3 *$ Energy of Hydrogen Atom
Equal Spacing Suggest Algebra Structure

Figure 16.2: Nonrelativistic spectrum of the hydrogen atom, replotted to emphasize the possibility of a dynamical algebra.

### 16.11.2 Scattering States

If $C>0$ we can choose $e^{-\theta}-C e^{\theta}=0$, so that the resulting equation becomes

$$
\begin{equation*}
\left(-2 \sqrt{C} \Gamma_{4}+B\right) u(r)=0 \tag{16.69}
\end{equation*}
$$

where as before $u(r)=e^{\theta M_{4}} R(r)$. Since the generator $\Gamma_{4}$ is noncompact, it has a continuous spectrum. The energy can be written in terms of the scaling factor $k \simeq e^{-\theta}$ with $E=\hbar^{2} k^{2} / 2 m$.

The asymptotic form of the wave function is $[6,8]$

$$
\begin{equation*}
R_{k, l}(r) \sim \sqrt{\frac{2}{\pi}} \sin \left(k r-\frac{\pi}{2} j+\frac{\alpha}{k}(\log (2 k r)+\delta(j))\right) \tag{16.70}
\end{equation*}
$$

where $\delta(j)=\arg [\Gamma(j+1-i(\alpha / k)]$ is part of the scattering phase shift, and the expression for $j$ is given in Equ.(16.68) above.

Remark: The angular momentum operators $L_{z}, L_{ \pm}$act on states shown as a single horizontal line in Figs. 16.1 and 16.2. The operators $M_{z}, M_{ \pm}$associated with the Laplace-Runge-Lenz vector act horizontally on the levels shown in these two figures. The operators $\Gamma_{z}, \Gamma_{ \pm}=\Gamma_{4} \pm i M_{4}$ act vertically on the levels shown in these figures. Since $[\mathbf{L}, \Gamma]=0$, the operators $\Gamma$ do not change the $m$ values of hydrogenic states.

Remark: The shift down operator $\Gamma_{-}$annihilates the ground state in a given angular momentum tower: $\Gamma_{-}\left\langle r \left\lvert\, N \begin{array}{c}l=N-1 \\ m\end{array}\right.\right\rangle=0$. Since the differential operators are known, this relation can be used, as was the relation $L_{-} Y_{m=-l}^{l}(\theta, \phi)=0$, to determine the radial wavefunction $\langle r \mid N, l=N-1\rangle$.

### 16.11.3 Quantum Defect

Multielecton atoms are complicated objects. If one of the electrons is promoted to a high lying level, it is on average far from the nucleus and the core electrons. Some simplifications can then be made in the description of its excited state spectrum. As the "Rydberg" electron approaches the core, the positive nuclear charge is less completely screened by the core electrons, and the electron is more strongly attracted than a simple $-1 / r$ potential suggests. It is possible to represented this extra atraction by adding a term of the form $-1 / r^{2}$ to the potential to represent penetration of the core electrons. To this end the potential used in the Schrödinger and Klein Gordan equations is $V(r)=-\frac{e^{2}}{r} \rightarrow-e^{2} / r-\mu_{l}\left(\hbar^{2} / 2 m\right) / r^{2}$. This perturbation produces a modification in the radial equation. The modification is encapsulated entirely in the change

$$
\begin{equation*}
A \rightarrow A^{\prime}=A+\mu_{l} \tag{16.71}
\end{equation*}
$$

This change produces a change in the value of $j \rightarrow j^{\prime}=j+\Delta j$, where $\Delta j=-\mu_{l} /(2 l+1)$ in the nonrelativistic case. This change produces a change in the bound state energy spectrum:

$$
\begin{equation*}
E_{N=n+l+1}=-\frac{m c^{2} \alpha^{2}}{2 N^{2}} \rightarrow-\frac{m c^{2} \alpha^{2}}{2(N+\Delta j)^{2}} \tag{16.72}
\end{equation*}
$$

The quantum defect $\Delta j$ causes the Rydberg states to be bound more strongly than in a pure hydrogen atom (without screening). The same change occurs in scattering states. There is an additional phase shift due to the core. The excess phase shift is

$$
\begin{equation*}
\Delta \phi=-\frac{\pi}{2} \Delta j+\frac{\alpha}{\pi} \arg (\Gamma[j+1+\Delta j-i(\alpha / k)]-\Gamma[j+1-i(\alpha / k)]) \tag{16.73}
\end{equation*}
$$

Remark: More accurate calculations of bound state spectra and scattering phase shifts employ more accurate representations of core screening (than $-1 / r^{2}$ ). Nevertheless, the results are the same: A quantum defect in the bound state energies translates, through analytic continuation, to a corresponding excess phase shift in the scattering states [7].

### 16.12 Conclusion

## Problems

11. Equivalence Principle: Assume two observers $S$ and $S^{\prime}$ are locked inside elevators without windows, so they cannot perceive the exterior world. Assume one elevator is sitting on the surface of the earth, so that the observer $S$ experiences a gravitational force $\mathbf{F}=m \mathbf{g}$ in the "down" direction. Assume that the other elevator is in "interstellar space" so that external gravitational forces "vanish", but that his elevator experiences an acceleration $\mathbf{g}$ in the "up" direction. If the "rest of the universe" "looks the same" to both observers, argue that you can represent a gravitational field by a local acceleration. This use of the Equivalence Principle is one of the foundations of the General Theory of Relativity. Now argue that the two observers can monitor the state of the $3^{\circ}$ thermal bachground radiation field. Argue that they can use this measurement to determine if an observer is at rest or in accelerated motion (i.e., g) with respect to the background. Finally, conclude that the Equivalence Principle, as used in General Relativity, is not necessarily compatible with the existence of the universal thermal radiation field (the new "aether") left over from the Big Bang.
12. In the presence of a uniform magnetic field $\mathbf{B}$ show that the vector potential $\mathbf{A}$ can be taken as $\mathbf{A}=\frac{1}{2} \mathbf{B} \times \mathbf{r}$, so that $\mathbf{B}=\nabla \times \mathbf{A}$. Derive the Klein-Gordon equation for an electron in a Coulomb potential and a uniform magnetic field. Take the nonrelativistic limit of this and derive the Schrödinger equation for an electron in the presence of these two fields.
13. Make the ansatz $E=m c^{2}+W$ in the Klein-Gordon equation and exhibit the terms in this equation that must be neglected in order to recover the nonrelativistic approximation, the Schrödinger equation.
14. Introduce spherical coordinates as follows: $(r, \theta, \phi)=\left(\theta_{3}, \theta_{2}, \theta_{1}\right)$ and

$$
\begin{align*}
& z=x_{3}=\theta_{3} \cos \theta_{2}  \tag{16.74}\\
& y=x_{2}=\theta_{3} \sin \theta_{2} \cos \theta_{1}  \tag{16.75}\\
& x=x_{1}=\theta_{3} \sin \theta_{2} \sin \theta_{1} \tag{16.76}
\end{align*}
$$

Show that $\mathcal{L}^{2}\left(S^{1}\right)=\partial^{2} / \partial \theta_{1}^{2}$. Show that

$$
\sin ^{2} \theta_{2} \mathcal{L}^{2}\left(S^{2}\right)=\left(\sin \theta_{2} \frac{\partial}{\partial \theta_{2}}\right)^{2}+\mathcal{L}^{2}\left(S^{1}\right)
$$

Generalize this result to $\mathcal{L}^{2}\left(S^{3}\right)$ recursively using $\mathcal{L}^{2}\left(S^{2}\right)$ and $\left(\partial / \partial \cos \theta_{3}\right)^{2}$. Do this more generally for $\mathcal{L}^{2}\left(S^{n}\right)$.
4. Carry out the steps indicated in Table 16.1.
a. Show that the singular points of Eq. (16.9) occur at $r=0$ and $r \rightarrow \infty$.
b. Show that in the neighborhood of the singular points

$$
\begin{array}{llll}
r=0 & \text { Eq. 16.9 } \rightarrow\left(\frac{d^{2}}{d r^{2}}+\frac{A}{r^{2}}\right) R(r)=0 & R(r) \simeq r^{\gamma} & \gamma(\gamma-1)+A=0 \\
r=\infty & \text { Eq.16.9 } \rightarrow\left(\frac{d^{2}}{d r^{2}}+C\right) R(r)=0 & R(r) \simeq e^{\lambda r} & \lambda^{2}+C=0
\end{array}
$$

Show that $\gamma=\frac{1}{2} \pm \sqrt{\left(\frac{1}{2}\right)^{2}-A}$ and $\lambda= \pm \sqrt{-C}$.
c. Show that if $\sqrt{\left(\frac{1}{2}\right)^{2}-A}$ is real, the solution with the positive sign is always square integrable in the neighborhood of $r=0$. Under what conditions is the solution with the negative sign square integrable? Show that if $C<0$ the solution $\pm \sqrt{-C}$ with the negative sign is always square integrable. What happens if $C>0$ ?
d. Show that a solution of the form $R(r)=r^{\gamma} e^{\lambda r} f(r)$ can be found where the function $f(r)$ is a simple ascending polynomial function.
e. Find the equation that the function $f(r)$ satisfies. Show that it is equivalent to the equation given in Table 16.1.
f. Represent the function $f(r)$ as an ascending power series: $f(r)=\sum_{j=0}^{\infty} f_{j} r^{j}$. Find the two-term recursion relation satisfied by the coefficients $f_{j}$. Show that the recursion relation is

$$
[(j+1) j+2 \gamma(j+1)] f_{j+1}+(2 \lambda \gamma+2 \lambda j+B) f_{j}=0
$$

Use this relation to show

$$
f(r)=\sum_{j=0} \frac{\Gamma(j+\gamma+(B / 2 \lambda))}{\Gamma(\gamma+(B / 2 \lambda))} \frac{\Gamma(2 \gamma)}{\Gamma(j+2 \gamma)} \frac{(-2 \lambda r)^{j}}{j!}
$$

g. If this series does not terminate, show that its asymptotic behavior as $r \rightarrow \infty$, determined from the behavior of $f_{j}$ as $j \rightarrow \infty$, is $f(r) \rightarrow e^{-2 \lambda r}$. Since $\lambda<0$ a square integrable solution is not possible.
h. Conclude that the function $f(r)$ must be a polynomial of finite degree. If the highest nonzero degree term present is $r^{n}$, so that $f_{n} \neq 0$ but $f_{n+1}=0\left(\Rightarrow f_{n+2}=f_{n+3}=\cdots=0\right)$, show that the quantization conditon $2 \lambda(n+\gamma)+B=0$ must be satisfied. Show that this leads to the quantization condition in terms of the three parameters $A, B, C$ that appears in Eq.(16.9):

$$
n+\frac{1}{2}+\sqrt{\left(\frac{1}{2}\right)^{2}-A}=\frac{B}{2 \sqrt{-C}}
$$

i. Use the values of the parameters $A, B, C$ given in Eq.(16.10) to solve for the energy eigenvalues of the Klein-Gordon and Schrödinger equations:

$$
E(n, l)=\frac{m c^{2}}{\sqrt{1+\frac{\alpha^{2}}{\left(n+\frac{1}{2}+\sqrt{\left.\left(l+\frac{1}{2}\right)^{2}-\alpha^{2}\right)^{2}}\right.}}} \quad W(n, l)=-\frac{1}{2} m c^{2} \alpha^{2} \frac{1}{(n+l+1)^{2}}
$$

Show that the polynomial solution is

$$
f(r)=\sum_{j=0}^{n} \frac{\Gamma(2 \gamma)}{\Gamma(j+2 \gamma)} \frac{n!}{(n-j)!j!}(2 \lambda r)^{j}
$$

The radial part of the wavefunction $\frac{1}{r} r^{\gamma} f(r) e^{\lambda r}$ has exactly $n$ nodes in the open interval $(0, \infty)$.
5. For a highly ionized atom with $Z$ protons in its nucleus and a single remaining electron, show that the potential is $Z e / r$ and the solutions of the relativistic and nonrelativistic equations are obtained by the replacement $\alpha \rightarrow Z \alpha$. How large can $Z$ become before the relativistic solution is clearly incorrect? (Hint: set $l=0$.)
6. Expand the relativistic energy in ascending powers of the fine structure constant to determine the relativistic corrections to the nonrelativistic energy. Show that, with $N^{\prime}=n+\frac{1}{2}+\sqrt{\left(l+\frac{1}{2}\right)^{2}-\alpha^{2}}$ and $N=n+l+1$

$$
\begin{gathered}
E(n, l)=\frac{m c^{2}}{\sqrt{1+\left(\frac{\alpha}{N^{\prime}}\right)^{2}}} \rightarrow m c^{2}-m c^{2} \frac{1}{2 N^{2}} \alpha^{2}+m c^{2}\left(\frac{3}{8 N^{4}}-\frac{1}{N^{3}(2 l+1)}\right) \alpha^{4} \\
+m c^{2}\left(-\frac{5}{16 N^{6}}+\frac{3}{2 N^{5}(2 l+1)}-\frac{2 N+3(2 l+1)}{2 N^{4}(2 l+1)^{3}}\right) \alpha^{6} \\
+m c^{2}\left(\frac{35}{128 N^{8}}-\frac{15}{8 N^{7}(2 l+1)}+\frac{6 N+9(2 l+1)}{4 N^{6}(2 l+1)^{3}}-\frac{2 N^{2}+3 N(2 l+1)+2(2 l+1)^{2}}{N^{5}(2 l+1)^{5}}\right) \alpha^{8}+\mathcal{O}\left(\alpha^{10}\right)
\end{gathered}
$$

7. The radial part of the wavefunction dies off like $e^{\lambda r}$ for large $r$, where $\lambda<0$ for bound states. The parameter $\lambda$ has the dimensions of length, and $a \simeq 1 /|\lambda|$ characterizes the size of a bound state orbit. Show that bound states with quantum numbers $(n, l)(N=n+l+1$ is the principal quantum number) have size scales

$$
\begin{array}{lll}
\text { Relativistic } & a(n, l)=\sqrt{\left(N^{\prime}\right)^{2}+\alpha^{2}} a_{\mathrm{B}} & N^{\prime}=n+\frac{1}{2}+\sqrt{\left(l+\frac{1}{2}\right)^{2}-\alpha^{2}} \\
\text { Nonrelativistic } & a(n, l)=N a_{\mathrm{B}} & N=n+l+1
\end{array}
$$

In these expressions $a_{\mathrm{B}}=\hbar^{2} / m e^{2}=0.529 \mathrm{~cm}$ is the Bohr radius: the characteristic size of the hydrogen atom in its ground state. By what percentage do the sizes of the atoms in the $(n, l)$ states differ between the relativistic and nonrelativistic treatments?
8. Many charged particles can form hydrogen-like atoms through their electrostatic interaction. Compute the energy spectrum for bound states of neutral atoms formed from a positively charged particle and a negatively charged particle drawn from this list of particles 16.3. For each the mass is given in terms of the particle rest energy.
9. The motion of a classical nonrelativistic particle in a $1 / r^{2}$ radial force field is a conic section: an elliptical orbit for bound states $(E<0)$; hyperbolic for scattering states $(E>0)$; and parabolic at the separatrix $(E=0)$. If the radial force field includes a radial $1 / r^{3}$ perturbation

$$
f=-\frac{K}{r^{2}}+\frac{C}{r^{3}}
$$

the trajectory has the form

$$
r=\frac{a\left(1-\epsilon^{2}\right)}{1+\epsilon \cos (\alpha \theta)}
$$

where $\alpha=\sqrt{1-\eta}, \eta=\frac{C}{K a}$. This can be treated as an ellipse that is slowly rotating, $\alpha \simeq 1$. In this case the parameters $a$ and $\epsilon$ have their usual meanings for elliptical orbits: $a$ is the semimajor axis and $\epsilon$ is the eccentricity. The ratio $\eta$ is a measure of the strength of the perturbation to the strength of the coulomb potential.

Table 16.3: Some particles that can be used to form hydreogen-like atoms.

| Particle | Rest Energy $(\mathrm{MeV})$ |
| :--- | ---: |
| electron $e^{ \pm}$ | 0.511 |
| mu meson $\mu^{ \pm}$ |  |
| tau meson $\tau^{ \pm}$ |  |
| proton, antiproton $p^{ \pm}$ |  |
| pi meson $\pi^{ \pm}$ |  |
| deuteron $d^{+}$ |  |
| tritium $t^{+}$ |  |
| sigma meson $\Sigma^{ \pm}$ |  |
| omega $\Omega^{-}$ |  |
| cascade meson $\Xi^{X X}$ |  |

a. Expand the relativistic energy $E=\sqrt{\left(m c^{2}\right)^{2}+(\mathbf{p} c)^{2}}-K / r$ to fourth order in $\mathbf{p}$ and show $E=\left(m c^{2}\right)+\left(p^{2} / 2 m\right)-\left(p^{2} / 2 m\right)^{2} /\left(2 m c^{2}\right)-K / r=m c^{2}+W$.
b. Replace the quartic term by $-\left(p^{2} / 2 m\right)^{2} /\left(2 m c^{2}\right)=-(W+K / r)^{2} /\left(2 m c^{2}\right)$ and expand. Show that the classical hamiltonian for the motion of the (special) relativistic particle is

$$
H=m c^{2}+\frac{p^{2}}{2 m}-\frac{K^{\prime}}{r}+\frac{C^{\prime}}{r^{2}}
$$

Evaluate $K^{\prime}$ and $C^{\prime}$ and show $K^{\prime}=K\left(1+W / m c^{2}\right)$ and $C^{\prime}=-K^{2} /\left(2 m c^{2}\right)$.
c. Argue that the classical motion involves a renormalized coupling $K \rightarrow K^{\prime}$ as well as a $1 / r^{3}$ component to the force, with $C=2 C^{\prime}$.
d. Show that the advance in the perihelion of the orbit is $\delta \theta \simeq \eta / 2$ per period.
e. Evaluate $\eta$ for the planet Mercury, for which $\epsilon=0.206$ and the period is $T=0.24$ year. Show that this amounts to about 7 " per century. The general relativistic correction is larger by a factor of 6 , and accounts for the observed advance in Mercury's perihelion of 42 "/ century.
f. The existence of precessing elliptical orbits is due to the "relativistic mass velocity" correction. This can be viewed from two perspectives. (1) Newton's equations are correct and the mass of the particle varies with its state of motion according to $m=m_{0} / \sqrt{1-(v / c)^{2}}$. (2) The mass of a particle is a constant of Nature and Newtons (nonrelativistic) equations of motion are not correct for relativistic particles, and must be modified. The author feels the second interperetation is far superior to the first.
X. (from http://en.wikipedia.org/wiki/Laplace-Runge-Lenz_vector) (Needs verification) When the attracting potential is central and nearly $1 / r$, the motion of a bound particle is nearly elliptical. It is useful to describe this motion as if it were elliptical, with the semimajor axis of the ellipse precessing in the plane of motion. Assume that the potential has the for $\mathbf{F}(r)=\left(-K / r^{2}+p(r)\right) \hat{\mathbf{r}}$, where $p(r)$ is a small perturbation. It has been shown that the rate at which the Runge-Lenz vector precesses is

$$
\omega=\frac{\partial}{\partial L}\left(\frac{1}{T} \int p(r) d t\right)=\frac{\partial}{\partial L}\left(\frac{m}{L T} \oint r^{2} p(r) d \theta\right)
$$

with $1 / r=\frac{m K}{L^{2}}\left(1+\frac{M}{m K} \cos \theta\right)$. If the perturbing term is of the form $C / r^{3}$ the integral is $C \times 2 \pi \frac{m K}{L^{2}}$. The perturbations due to Special and General Relativity are

$$
\begin{array}{lll}
\text { Special Relativity } & C=\frac{K L^{2}}{2 m^{2} c^{2}} & \omega=\frac{\pi K^{2}}{T L^{2} c^{2}} \\
\text { General Relativity } & C=6 \times \frac{K L^{2}}{2 m^{2} c^{2}} & \omega=\frac{6 \pi K^{2}}{T L^{2} c^{2}}
\end{array}
$$

Bob: Verify This! Why is $\omega$ independent of the planetary mass $m$ ? Determine how the relativistic precession $\omega$ scales (cf. Problem X.XX, last chapter) with planetary distance from the sun. What is the precession for the earth? Use $\omega=42^{\prime \prime} /$ cent for Mercury and the following distance ratios:
$\begin{array}{cccccccc}\text { Mercury } & \text { Venus } & \text { Earth } & \text { Mars } & \text { Jupiter } & \text { Saturn } & \text { Uranus } & \text { Neptune } \\ 0.39 & 0.72 & 1.00 & 1.52 & 5.20 & 9.54 & 19.18 & 30.06\end{array}$
10. The action of the angular momentum shift down operator $L_{-}$on the lowest $m$-value spherical harmonic for a given value of $l$ is zero: $L_{-} Y_{m=-l}^{l}(\theta, \phi)=0$. Use the coordinate representation for $L_{-}$to compute this function.
a. Write $Y_{m}^{l}(\theta, \phi)=P_{-l}^{l}(\theta) e^{-i l \phi}$ and show

$$
\left(-\frac{\partial}{\partial \theta}+i \frac{\cos \theta}{\sin \theta} \frac{\partial}{\partial \phi}\right) P_{-l}^{l}(\theta) e^{-i l \phi}=e^{-i l \phi}\left(-\frac{\partial}{\partial \theta}+l \frac{\cos \theta}{\sin \theta} \frac{\partial}{\partial \phi}\right) P_{-l}^{l}(\theta)
$$

b. Show $P_{-l}^{l}=(\sin \theta)^{l}$ satisfies this equation.
c. This function is not normalized to unity over the sphere. Normalize it by introducing a normalization coefficient $N_{l}$ and enforcing the condition

$$
\int_{0}^{\pi} d \theta \sin \theta \int_{0}^{2 \pi} d \phi\left|N_{l} \sin ^{l} \theta e^{-i l \phi}\right|^{2}=1
$$

d. Show that $N_{l}=\sqrt{\frac{1}{4 \pi}} \sqrt{\frac{(2 l+1)!!}{(2 l)!!}}$.
e. This leads the the simple recursion relation for normalization coefficients for the $Y_{ \pm l}^{l}(\theta, \phi)$ :

$$
N_{l+1}=\sqrt{\frac{2 l+1}{2 l}} N_{l}
$$

Compare these results with Table 16.2 using initial condition $N_{0}=\sqrt{\frac{1}{4 \pi}}$. Compute $N_{3}$.
f. Use the numerical value of the matrix elements $\left\langle\begin{array}{c}l \\ m^{\prime}\end{array}\right| L_{+}\left|\begin{array}{c}l \\ m\end{array}\right\rangle=\sqrt{\left(l+m^{\prime}\right)(l-m)} \delta_{m^{\prime}, m+1}$ and the coordinate representation of the shift up operator $L_{+}$to construct the correctly normalized shperical harmonics $Y_{m}^{l}(\theta, \phi)$.
16. Use methods similar to those described in Problem 10 to construct the radial wavefunctions for hydrogenic atoms with extreme orbital angular momentum quantum numbers: $l=N-1$, where in general the Principle quantum number $N=n+l+1$. These functions have no nodes in the interval $(0, \infty)$ (since $n=0$ ).
12. Show $\frac{d}{d t}\left(\frac{\mathbf{r}}{r}\right)=\frac{\dot{\mathbf{r}}(\mathbf{r} \cdot \mathbf{r})-\mathbf{r}(\mathbf{r} \cdot \dot{\mathbf{r}})}{r^{3}}=-\frac{\mathbf{r} \times(\mathbf{r} \times \dot{\mathbf{r}})}{r^{3}}$.
13. $\mathbf{r}$ is the position vector from the sun to a planet, or from the proton to the electron in the hydrogen atom, $\mathbf{L}=\mathbf{r} \times \mathbf{p}$ is the orbital angular momentum, and $\mathbf{M}$ is the Laplace-Runge-Lenz vector.
a. $\mathbf{M} \cdot \mathbf{L}=0$.
b. $\mathbf{M} \cdot \mathbf{M}=\frac{2 \mathbf{L} \cdot \mathbf{L}}{m}\left(\frac{\mathbf{p} \cdot \mathbf{p}}{2 m}-\frac{K}{r}\right)+K^{2}$.
c. $\mathbf{M} \cdot \mathbf{r}=\frac{\mathbf{L} \cdot \mathbf{L}}{m}-K r$.
d. $\mathbf{M} \cdot \mathbf{r}=M r \cos \theta$.
e. $r=\frac{\mathbf{L} \cdot \mathbf{L} / m K}{1+(M / K) \cos \theta}$.
f. Compare this result to the standard solution of the trajectory equations for motion in a $1 / r$ potential to conclude: $L^{2} / m K$ is the semimajor axis of the elliptical orbit and $\epsilon=M / K$ is the eccentricity of the orbit.
g. Conclude that the Laplace-Runge-Lenz vector is a constant of motion that points to the perihelion of the elliptical orbit.
15. Show that $\mathbf{A} \cdot \mathbf{A}=\frac{-1}{4 \hbar^{2}}\left(\mathbf{L} \cdot \mathbf{L}+\mathbf{M}^{\prime} \cdot \mathbf{M}^{\prime}+\mathbf{L} \cdot \mathbf{M}^{\prime}+\mathbf{M}^{\prime} \cdot \mathbf{L}\right)$. Show that $\mathbf{B} \cdot \mathbf{B}$ has a similar expression. Show that the two expressions are equal since $\mathbf{L} \cdot \mathbf{M}=\mathbf{M} \cdot \mathbf{L}=\mathbf{0}$.
X. Show that the inverse of the stereographic projection given in eq.(16.36) is

$$
\frac{\mathbf{p}}{p_{0}}=\frac{\mathbf{u}}{1-\mathbf{u} \cdot \mathbf{w}}
$$

X. Compute $p_{x}=\mathbf{p} \cdot \mathbf{M} / M$ and $p_{y}=\mathbf{p} \cdot \mathbf{W} / W$. Show $p_{x}^{2}+\left(p_{y}-a\right)^{2}=r^{2}$. Explicitly compute the displacement vector $a$ (i.e., $(0, a)$ ) and the radius $r$ of circular motion. Show that circles in $R^{3}$ lift to circles in $S^{3} \subset R^{4}$ under the stereographic projection of Eq.(16.36). Show that circles in $S^{3}$ project back down to circles in $R^{3}$ under the inverse transformation.
16. Show that the number of independent monomials of the form $x^{a} y^{b} z^{c}$, with $a, b, c$ nonnegative integers and $a+b+c=l$ is $N(l, 3)=(l+3-1) / l!(3-1)!$. In $N$-dimensional space show that the number of homogeneous polynomials of degree $l$ in $x_{1}, x_{2}, \ldots x_{N}$ is obtained by replacing $3 \rightarrow N$ in this expression. This is the Bose-Einstein counting statistic.
a. Show that the functions $r^{l} Y_{m}^{l}(\theta, \phi)$ are homogeneous polynomials in $x, y, z$ of degree $l$.
b. Show that the number of independent spherical harmonics of degree $l$ is the difference between the number of homogeneous polynomials of degree $l$ and $l-2$ on three variables: $\operatorname{dim}\left\{Y_{m}^{l}\right\}=$ $N(l, 3)-N(l-2,3)=2 l+1$.
c. After stereographic transformation into four dimensions, the hydrogen wavefunctions in the momentum representation are spherical harmonics in four variables. Show that the number of spherical harmonics of degree $n$ is $\operatorname{dim}\left\{\mathcal{Y}_{l m}^{n}\right\}=N(n, 4)-N(n-2,4)=(n+1)^{2}$.
d. Construct homogeneous polynomials of degree $0,1,2$ and the spherical harmonics associated with these homogeneous polynomials. Take the inverse Fourier transform of these spherical harmonics to obtain the hydrogen atom wavefucntions $\psi(\mathbf{x})_{n l m}$ for $n=0,1,2 ; l=0, \ldots, n-1$; and $-l \leq m \leq+l$.
e. Show that the recursive relation used to build up a Pascal triangle can be written in the symmetric form

$$
\frac{(a+b+1)!}{\left(a+\frac{1}{2}\right)!\left(b+\frac{1}{2}\right)!}=\frac{(a+b)!}{\left(a-\frac{1}{2}\right)!\left(b+\frac{1}{2}\right)!}+\frac{(a+b)!}{\left(a+\frac{1}{2}\right)!\left(b-\frac{1}{2}\right)!}
$$

where $a$ and $b$ are half odd integers: $\frac{1}{2}, \frac{3}{2}, \frac{5}{2}, \ldots$.
f. Show homogeneous polynomials satisfy the recursion relation: $N(l, d)=N(l, d-1)+N(l-1, d)$.
g. Use this result to derive the following recursion relation for the dimensions of the spaces of spherical harmonics on spheres $S^{n}$ and $S^{n-1}$ :

$$
\operatorname{dim} \mathcal{Y}^{l}\left(S^{n}\right)=\operatorname{dim} \mathcal{Y}^{l-1}\left(S^{n}\right)+\operatorname{dim} \mathcal{Y}^{l}\left(S^{n-1}\right)
$$

For the case $n=3$ this gives $(l+1)^{2}=l^{2}+(2 l+1)$. The initialization for all $n$ is $\mathcal{Y}^{0}\left(S^{n}\right)=$ $1=\operatorname{dim} \mathcal{Y}^{0}\left(S^{n}\right)$.
h. $\operatorname{dim} \mathcal{Y}^{l}\left(S^{n}\right)=\frac{(l+n-2)!}{l!(n-1)!}(2 l+n-1)$.
XX. D-Dimensional Coulomb Problem: In $D$-dimensional space the Schrödinger equation for the Kepler problem is Eq. (16.4) in the relativistic case and Eq. (16.5) in the nonrelativistic case. The only difference is that the Laplacian $\nabla^{2}$ is on $D$ coordinates rather than three. In this case the Laplacian operator is

$$
\nabla^{2}=\left(\frac{1}{r^{D-1 / 2}} \frac{\partial}{\partial r} r^{D-1 / 2}\right)^{2}+\frac{\mathcal{L}^{2}}{r^{2}}
$$

The angular part of the Laplacian operator, $\mathcal{L}^{2}$, acts on spherical harmonics on $S^{D-1}, \mathcal{Y}^{l}\left(S^{D-1}\right)$. These spjherical harmonics are eigenfunctions of this (Laplace-Beltrami) operator with eigenvalue $-\left[(l+\alpha)^{2}-\alpha^{2}\right]$, and $\alpha$ is a quantity that depends on the Lie algebra of $S O(D)$ : it is half the sum over all positive roots. For the Lie algebras of the orthogonal roots the coefficient of the sum that is important for the action of this second order invariant is $\alpha=D-2$.
a. Show that $\psi(\mathbf{x})=\frac{1}{r^{D-1 / 2}} \mathcal{Y}^{l}$ (angles) is a clever ansatz that reduces the Schrödinger equation in $D$ dimensions to the form of Eq. (16.4) in the relativistic case and Eq. (16.5) in the nonrelativistic case.
b. Show that the only change in Eq. (16.10) is the replacement $\left(l+\frac{1}{2}\right)^{2}-\left(\frac{1}{2}\right)^{2} \rightarrow\left(l+\frac{D-2}{2}\right)^{2}-\left(\frac{D-2}{2}\right)^{2}$ in column A.
c. Show that the relativistic and nonrelativistic energies shown in Eq.(16.12) change as follows:

$$
\begin{array}{llll}
\text { Relativistic } & N^{\prime} & \rightarrow & n+\frac{1}{2}+\sqrt{\left(l+\frac{1}{2}\right)^{2}+l(D-3)-\alpha^{2}} \\
\text { Non Relativistic } & N & \rightarrow & n+\frac{1}{2}+\sqrt{\left(l+\frac{1}{2}\right)^{2}+l(D-3)}
\end{array}
$$

17. Compute the quantum defect in heavy atoms by using the Klein-Gordan equation and a $-1 / r^{2}$ perturbation. Show that the bound state energy and scattering phase shifts are given by the substitution $l(l+1) \rightarrow l(l+1)-\mu_{l}$. Argue that electrons in the $s$ state penetrate the core much more deeply (on average) and $p$-state electrons (than $d$-state electrons, ...) so that $\mu_{0} \gg \mu_{1}>\cdots$.
18. The isotropic harmonic oscillator in $n$ dimensions has hamiltonian

$$
H=\sum_{i=1}^{n} \hbar \omega\left(a_{i}^{\dagger} a_{i}+\frac{1}{2}\right)
$$

a. Show that the Lie algebra of its geometric symmetry group is spanned by the angular momentum operators $L_{i j}=a_{i}^{\dagger} a_{j}-a_{j}^{\dagger} a_{i}=-L_{j i}$.
b. Show that the Lie algebra of its dynamical symmetry group is spanned by the angular momentum operators together with the quadrupole tensor operators $Q_{i j}=a_{i}^{\dagger} a_{j}+a_{j}^{\dagger} a_{i}=+Q_{j i}$.
c. Show that one spectrum generating algebra includes the operators $\mathbf{L}$ and $\mathbf{Q}$ as well as the single boson operators $a_{i}^{\dagger}$ and $a_{j}$, as well as their commutator $\left[a_{i}, a_{j}^{\dagger}\right]=1$. Show that this algebra is nonsemisimple and describe its structure.
d. Show that another spectrum generating algebra consists of the operators $\mathbf{L}$ and $\mathbf{Q}$ as well as the two boson creation operators $a_{i}^{\dagger} a_{j}^{\dagger}$ and two boson annihilation operators $a_{i} a_{j}$. Show that this algebra is simple and describe its structure. Show that this spectrum generating algebra does not couple all the states that exist: "parity" is an invariant, where "parity" is even or odd according to whether the number of excitations in the spectrum is evend or odd.
